Manda (1) Publications of CHRISTOPHER SOWER COMPANY, Philadolphia. Brooks's Normal Geometry and Trigonometry. By the aid of Brooks's Geometry the principles of this beautiful science can be easily acquired in one term. It is so condensed that the amount of matter is reduced one half, and yet the chain of logic is preserved innet and nothing essential is omitted. The subject is made interesting and practical by the introduction of Theorems for original demonstration, Practical Problems, Mensuration, etc., in their appropriate places. The success of the work is very remarkable. Brooks's Plane and Solid Geometry. Complete. In this new work the subject has been fully developed with all the clear reasoning, broad analyses, and Incid explanation for which the author has become famous. Colleges and schools of the Brooks's Normal Algebra.

highest grade will find it a work they have been wanting,

Key. \$1.05*.

The many novelties, scientific arrangement, clear and coacise definitions and principles, and masterly treatment contained in this quite new work make it extremely popular. Each topic is so clearly and fully developed that the next follows easily and naturally. Young pupils can hundle it, and should take it up before studying Higher Arithmetic. Like the Geometry, if can be readily mastered in one term. It only needs introduction to make it indispensable. Kev. \$1.05%.

Peterson's Familiar Science. Peterson's Familiar Science, 18mo.

This popular application of acieuce to every-day results is universally liked, and has an immense circulation. No school should be without it. Inexperienced teachers have no dimently in teaching it.

Griffin's Natural Philosophy.

BY LA ROY F. GRIFFIN.

PROF. OF NATURAL SCIENCES AND ASTRONOMY, LAKE FOREST UNIVERSITY, ILL. Professor Griffin presents his subject so simply, clearly and logically, his definitions are so brief and yer clear, and his experiments so vivid and impressive, that the subject is easily mastered and firmly impressed on the student. All the latest applications of the science to Electric Lights, Telephone, Phonograph, Electro Plating, Magnetic Engines, Telegraphing, etc., are lucidly explained.

PREFACE.

Progress in education is symbolized in the multiplication and improvement of text-books. They are showered upon us like the flowers of spring-time, until a new text-book is no longer a novelty. To-day the author sends forth this little volume on what it is hoped may be a mission of usefulness. It comes modestly claiming a welcome from the public as an addition to our educational literature, and in support of such claim the following statement of its object and peculiarities is presented.

Our text-books upon Geometry, though well adapted to our higher institutions, are, for a large class of schools, toth too voluminous and difficult. In many of our Academies, Seminaries, High and Normal Schools, the time allotted to Geometry is too brief to allow the pupil to complete more than four or five books of the ordinary text-book; in consequence of which, all of that most important and practical part treating of the measurement of the surface and volume of prisms, pyramids, cylinders, cones, and spheres, must be omitted. To supply this defect and enable the pupil to acquire a fuller knowledge of the subject, the present volume has been written.

General Features.—In its adaptation to the class of pupils designated, this work is characterized by four general features. First, an abbreviation of the ordinary text-books; second, a simplification, so far as possible, of the methods of demonstration usually employed; third, examples to impart the power of making a practical application of the principles of the science; fourth, undemonstrated theorems, to cultivate the power of

original thought and investigation. These general characteristics will be briefly noticed.

ABBREVIATION.—In the abbreviation of the subject, the object has been to present the most valuable part of Geometry in about one-half of the space usually devoted to it. This object has been accomplished in two ways:—first, by an omission of all that is not essential to the final results; and secondly, by such a modification of the remainder as to preserve the chain of logic intact. The difficulty of this will be appreciated by those who remember that many propositions, apparently of little importance, are essential to the proof of others which follow them.

SIMPLIFICATION.—Much care has been taken to simplify the subject as far as possible. The author has endeavored to give the very simplest methods of treating special subjects, such as parallels, areas, volumes, the circle, etc.; and also the clearest and most concise methods of demonstrating individual theorems. The method of infinites, as applied to incommensurable quantities, the circle, and the sphere, has contributed largely to this simplification and abbreviation. This method is regarded by some as less satisfactory than the method of reductio ad absurdum, or the method of limits; but it will be remembered that it is supported by the authority of our most eminent mathematicians, and, being so much more simple and concise, is believed to be preferable in a brief work like this.

Applications.—A radical defect of most of our text-books upon Geometry is that they present the subject so abstractly, that when the pupil has completed his course he is often unable to make any practical application of what he has learned. This defect has been supplied by the presentation of a collection of practical examples at the close of each book. With these, the pupil can see the application, the practical value of what he is doing, and will not only be able to make use of his knowledge, but will be incited to study the subject with more interest and earnestness.

THEOREMS FOR ORIGINAL THOUGHT .- Another general defect of

our text-books upon Geometry is the lack of matter for original thought, for the training of the inventive powers of the student. The pupil is required to learn the demonstrations of the text-book, but he has no undemonstrated theorems to test his own geometrical powers, and to train him in reasoning independently of the text-book. In view of this general defect, a collection of theorems for original thought has been given at the close of each book.

Geometry, in both the respects mentioned, has been treated quite differently from arithmetic and algebra. In these latter works, we have generally a large class of problems both for the application of the principles and the exercise of original thought. It is proper to remark, too, that several authors have realized this defect of Geometry, and have occasionally given some practical problems, and, in one or two instances, a collection of undemonstrated theorems. In the present work, such problems and theorems are an essential and prominent part of the plan.

Special Features.—The attention of teachers is also respectfully invited to the following special features of the work:

- 1. The Systematic Arrangement of the subject-matter, it is thought, will be an acceptable feature of the work.
- 2. The Analysis at the beginning of each book is supposed to be valuable in giving the pupil a general idea of the object of the book, and thus often indicating the course of reasoning in its development.
- 3. The Doctrine of Parallels, resulting from the modern definition of an angle and parallel lines, now adopted by several authors, is here presented in its most simple and concise form.
- 4. The Subject of Areas in Book III., and Volumes in Book VI., are presented with great conciseness and simplicity by the use of the doctrine of infinites and indivisibles.
- 5. The treatment of the circumference and area of a circle, in their relation to π , is much more simple and logical than any thing the author has met. It is confidently believed that it will give pupils a clearer view of the subject than they usually acquire in the study of other text-books.

MENSURATION.—A formal treatise upon Mensuration is also appended, although the most of it is really presented in the practical exercises. A few rules are given without demonstration; such omissions may be supplied by the teacher.

TRIGONOMETRY.—The little treatise on Trigonometry presents the elements of the subject briefly, and contains about as much as the advanced pupils in our ordinary academies, seminaries, etc. should be required to learn. A short treatise on Analytical Trigonometry is appended for those who have time to study this very interesting and useful subject. The Trigonometry and Geometry will be bound together, and also separately, to accommodate schools of different grades.

A general acknowledgment of indebtedness is due to those who have previously written upon the subject of Geometry, especially to American and French authors, many of whose works have been examined with great interest and profit.

Thanking my friends for the generous appreciation bestowed upon my previous labors, I send forth this little volume, hoping that it may be as kindly welcomed, and that, in its mission of usefulness, it may aid in awakening a deeper interest in the beautiful science of form,—a science over which the ancient sages mused with such deep enthusiasm, and to which the achievements of modern art and invention are so largely indebted.

EDWARD BROOKS.

HISTORY

OF

GEOMETRY AND TRIGONOMETRY.

Geometry is generally supposed to have had its origin in Egypt, where the annual overflowing of the Nile obliterated the landmarks and rendered it necessary to have recourse to mathematical measurement to re-establish them. This origin is indicated by the term itself, Geometry being from two Greek words, γn , earth, and $\mu \epsilon r \rho o \nu$, measure, signifying, literally, the measurement of the earth. But, whatever may have been the origin of the term, the natural tendency of the human mind to compare things in respect of their forms and magnitudes is so universal, that a geometry more or less perfect must have existed since the first dawn of civilization.

Geometry, originating in Egypt, is supposed to have been introduced into Greece by Thales, who lived about the year 650 B.C. Pythagoras, who lived about 570 B.C., was one of the earliest Greek geometers. He is supposed to have discovered the following principles:—I. Only three plane figures can fill up the space about a point; 2. The sum of the angles of a triangle equals two right angles; 3. The celebrated proposition of the square on the hypothenuse. Some say that in honor of this last discovery he sacrificed one hundred oxen. Plutarch says but one ox. Cicero doubts even that, as it was in opposition to his doctrines to offer bloody sacrifices, and suggests that they may have been images made of flour or clay.

The next geometer of eminence was Anaxagoras, who composed a treatise on the quadrature of the circle. Plato, the "poetical philosopher," delighted in the science, and cultivated it with great success, as is proved by his simple and elegant solution of the duplication of the cube. About fifty years after the time of Plato, Euclid collected the propositions which had been discovered by his predecessors, and formed of them his famous "Elements,"—a work of such eminent excellence that by many it is regarded, even at the present day, as the best text-book upon the subject of Elementary Geometry. It consists of fifteen books, thirteen of which are known to have been written by Euclid; but the fourteenth and fifteenth are supposed to have been added by Hypsicles of Alexandria.

Apollonius of Perga, about 250 years B.c., composed a treatise on Conic

Sections, in eight books. He is said to have given them their names, parabola, etc. About the same time flourished Archimedes, who distinguished himself in Geometry by the discovery of the beautiful relation between the sphere and cylinder. See Theorem*XI. Book VII. He also distinguished himself by his work on conoids and spheroids, by his discovery of the exact quadrature of the parabola, and his very ingenious approximation to that of the circle.

Other geometers of eminence followed, among whom the most illustrious, perhaps, were Pappus and Diophantus; but the Greek Geometry, though it was afterward enriched by many new theorems, may be said to have reached its limits in the hands of Archimedes and Apollonius, and a long interval of seventeen centuries elapsed before this limit was passed. In 1637, Descartes published his Geometry, which contained the first systematic application of algebra to the solution of geometrical propositions. Soon after this followed the discovery of the infinitesimal calculus of Leibnitz and Newton; and from that time to the present Geometry has shared in the general progress of all mathematical sciences.

TRIGONOMETRY.—Trigonometry, it is generally believed, originated with the Greek astronomers of Alexandria. The solutions of the most useful cases of spherical triangles have been known from the time of Hipparchus, and the fundamental formulæ appear in the Analemma of Ptolemy.

The Greeks used the chords of the double arcs, instead of the sines. The sines, or semi-chords, were introduced by the Arabians, probably by the astronomer Albateguius. To the Arabs, who preserved and cultivated the sciences during the dark ages, this science is indebted also for several other improvements. Regiomontanus introduced the tangents, which did much to simplify the calculations.

The term sine seems to be derived from the Latin sinus, a bosom; the arc is supposed to represent a bow, and thus gets its name; the string, half of which represents the sine of half the arc, would come against the heart or bosom; hence the name sine. The terms tangent and secant are naturally derived from the old geometrical definitions. The cosine and co-secant of an arc mean the sine and secant of the complement, the co being merely an abbreviation of complement. They were first introduced by Gunter.

There are two methods of treating Trigonometry, known as the analytical and synthetic methods. The synthetic method regards the trigonometrical functions as lines, or geometrical magnitudes, and develops the science according to the laws of geometrical reasoning. The analytical method regards these functions as ratios or numbers, and develops the science by means of analytical formulas.

The modern or analytical method is superseding the ancient or geometrical method. This method is said to have been first introduced by Dr. Peacock. Professor De Morgan, however, one of the first English authorities, tells us that "Rheticus, who gave the first complete trigonometrical table, and invented the secant and co-secant to complete it, used the method of ratios."

LOGARITHMS.—Logarithms were invented by Lord Napier, Baron of Merchiston, in Scotland. His work upon them was first published in 1614; though it is probable that he had commenced the investigation of them as early as 1594. The invention is regarded as one of the most useful ever made. It gave the author so high a reputation that Kepler dedicated 2 work to him in 1617, and succeeding mathematicians have paid him the highest compliments.

Napier's system of logarithms was afterward improved by Henry Briggs, a contemporary of the inventor, and Professor of Geometry in Gresham College. Assuming 10 for the basis, he constructed a system of logarithms corresponding to our system of numeration, which is much more convenient for the ordinary purposes of calculation. The two systems are distinguished as the Napierian and Briggean, or the Hyperbolic and Common logarithms. The former are called Hyperbolic because they represent the area of a rectangular hyperbola between its asymptotes; the latter are called Common because they are those in common use.

Briggs calculated the logarithms to 14 places, with the index of all numbers between 1 and 20,000, and between 90,000 and 100,000, and published them in 1624. Adrian Vlacq, a native of Holland, computed the logarithms of numbers between 20,000 and 90,000, and thus completed what Briggs had begun: he reduced the tables, however, to 10 decimal places. Vlacq's treatise was published in 1628, and contained the logarithms of all numbers up to 100,000, and also the logarithms of the sines, tangents, and secants of every minute of the quadrant. In 1623, he published a work containing the logarithmic sines, cosines, tangents, and cotangents for every ten seconds of the quadrant, calculated from the natural sines, etc. of the Opus Palatinum of Rheticus.

In the same year the Trigonometrica Britannica was published at Gouda, which contained the logarithmic sines and tangents for the 100th part of every degree of the quadrant, together with a table of natural sines, tangents, and secants. These had been computed by Briggs. Since then, many different tables have been published. The most complete are those of Vlacq; but these are very scarce. Hutton's Logarithms and Babbage's Logarithms of Numbers are among the most accurate and convenient. For more information upon the subject, see Brande's Encyclopedia, from which most of this history is collated.

SUGGESTIONS TO TEACHERS.

THE author desires to present the following suggestions to those who may use this work:

- 1. Young pupils should have a preliminary drill upon concrete Geometry before taking up the text-book. Let them be required to cut out triangles, squares, etc. from paper, give their names, compare them, and draw them upon the board. In this manner a general idea of the subject, the figures treated of, and even the method of reasoning, may be obtained, and the transition from this to the abstract will be simple and easy.
- 2. In the recitation, the pupil should be required to construct his diagram upon the blackboard without the aid of the text-book, and then enunciate and demonstrate the theorem, care being taken that the language and reasoning be accurate. At the close of the demonstration, those of the class who have noticed errors, upon being called upon by the teacher, should rise and point them out; after which the teacher may make any criticisms or explanations he may think proper.
- 3. With quite young pupils, and those whose time for the study is limited, the theorems for original thought may be omitted; with others, however, these exercises will be found to be of great value. They can be given in connection with the demonstrations of the book, or lessons may be assigned upon them after completing the book to which they belong, or they may be omitted until review. The latter method will be generally preferred.

The Practical Exercises should be solved by all classes. The easier problems may be assigned in connection with the theorems which they illustrate; the others may be deferred until the book upon which they depend is completed. The most difficult problems may be omitted until the whole Geometry is completed.

ELEMENTARY GEOMETRY.

INTRODUCTION.

LESSON I

SUBJECT-MATTER OF GEOMETRY.

EVERY object that we can see occupies some portion of space, and has extent and form. If we consider some object, as this book, for instance, we will perceive that it has length, breadth, and thickness. These are called the dimensions of the book.

If, now, we remove the book from before us, we can still imagine the space which it filled to be in the form of a book. This space, of course, will not be a material thing like the book, but it will have form and extent the same as the book had. Such definite portions of space, their forms and extent, are the things considered in Geometry.

These limited portions of space are called *Volumes*. A volume has length, breadth, and thickness, and these are called its dimensions. We should be careful to distinguish the geometrical volume, which is a portion of space, from the solid body, which occupies space. The one is material, the other is immaterial; the one is real body, the other is ideal body or pure form. It is ideal body or pure form that is treated of in Geometry.

SUGGESTIONS TO TEACHERS.

THE author desires to present the following suggestions to those who may use this work:

- 1. Young pupils should have a preliminary drill upon concrete Geometry before taking up the text-book. Let them be required to cut out triangles, squares, etc. from paper, give their names, compare them, and draw them upon the board. In this manner a general idea of the subject, the figures treated of, and even the method of reasoning, may be obtained, and the transition from this to the abstract will be simple and easy.
- 2. ELEMENTARY GEOMETRY.

INTRODUCTION.

LESSON I

SUBJECT-MATTER OF GEOMETRY.

EVERY object that we can see occupies some portion of space, and has extent and form. If we consider some object, as this book, for instance, we will perceive that it has length, breadth, and thickness. These are called the dimensions of the book.

If, now, we remove the book from before us, we can still imagine the space which it filled to be in the form of a book. This space, of course, will not be a material thing like the book, but it will have form and extent the same as the book had. Such definite portions of space, their forms and extent, are the things considered in Geometry.

These limited portions of space are called *Volumes*. A volume has length, breadth, and thickness, and these are called its dimensions. We should be careful to distinguish the geometrical volume, which is a portion of space, from the solid body, which occupies space. The one is material, the other is immaterial; the one is real body, the other is ideal body or pure form. It is ideal body or pure form that is treated of in Geometry.

Let us now consider this ideal body or volume a little more closely. First, we will notice that it is distinctly separated from the surrounding space. That which so separates it is called a *Surface*; and, since that which bounds the volume forms no part of the volume, it will be seen that a surface has no thickness, and possesses, therefore, but two dimensions, length and breadth.

If we consider one of these bounding surfaces, we will see that it also is limited or bounded. That which limits a surface is called a *Line*; and since that which limits a surface forms no part of the surface, it is seen that a line has only one dimension,—length.

Again, if we examine one of these lines, we will see that its ends are limited. This limit is called a *Point*; and, since the limit forms no part of the line, a point has neither length, breadth, nor thickness, but position only.

Now, although we have considered a point as the limit of a line, a line as the limit of a surface, and a surface as the limit of a volume, yet each of these may be regarded in a purely abstract manner, distinct from each other. Thus, we may consider points without regard to lines, lines without reference to surfaces, and surfaces without reference to volumes.

We have now attained a conception of the ideas of Geometry by passing from a body to an abstract volume, from this volume to a surface, from a surface to a line, and from a line to a point. This is the method of analysis, and is, without doubt, the method in which these ideas were primarily attained. They may, however, also be attained by synthesis, in the following manner.

Fix upon the idea of a point in space. Now, suppose

this point to move, and we have a line; suppose the line to move in a particular manner, and we have a surface; suppose the surface to move, and we have a volume.

These lines, surfaces, and volumes, of which we have attained the idea, are the fundamental quantities of Geometry. A quantity, you will remember, is any thing that can be measured. When one line crosses another, their divergence may be measured: hence we have a fourth kind of geometrical quantity, called *angles*. We are now prepared to define Geometry.

Geometry is that science which treats of the properties and relations of geometrical magnitudes. Its subject-matter are lines, surfaces, volumes, and angles.

LESSON II.

REASONING OF GEOMETRY.

THE subject-matter of Geometry, we have seen, are lines, surfaces, volumes, and angles. These general conceptions give rise to many special forms; these special forms are described, and such descriptions constitute the *Definitions* of the science.

When we consider these special forms of quantity, as well as quantity in general, we perceive some truths concerning them that are self-evident,—that must be true, since they cannot be conceived as untrue. These self-evident truths are called Axioms.

The science of Geometry begins with these primary ideas of space and the self-evident truths arising out of them, and from these, as a basis, rises to the higher truths by a process of reasoning. The axioms and definitions are,

therefore, said to be the basis of the science of Geometry. The definitions present the subjects upon which we reason; the axioms give the laws which guide us in the reasoning process. From these we trace our way, step by step, to the loftiest and most beautiful truths of the science, by the simple process of comparison. This process of comparison is called *reasoning*; and to this we now call attention.

Reasoning.—All Reasoning is comparison. A comparison requires a standard or basis, and this standard is the simple, the axiomatic, the known. To these we bring the complex, the theoretic, the unknown, and learn to understand them by comparing the complex with the simple, the theoretic with the axiomatic, the unknown with the known.

There are two distinct methods of geometrical reasoning, which may be distinguished as the analytic and synthetic methods. The analytic method is adapted to the discovery of truth; the synthetic method, to the proving of a truth when it has already been discovered.

Synthetic Method.—The synthetic method, which is generally employed in proving a truth which is already known, is called demonstration. There are two distinct methods of demonstration, called the Direct and the Indirect Method.

The simplest form of the *Direct Method* is that in which figures are directly compared by applying one to another. This is called the method by *superposition*. The more general form of the direct method is that in which truths are proven by a reference to the definitions and axioms, or some principle previously proven.

The Indirect Method, known as the reductio ad absurdum, consists in supposing the proposition to be proven not to

be true, and then showing that such an hypothesis leads to a contradiction of some known truth. This is frequently used to prove the converse of a proposition, when there is no good direct method; it is also used in incommensurable quantities.

There are two errors of demonstration into which young pupils are liable to fall. The first is called *Reasoning in a Circle*; the second is *Begging the Question*. We reason in a circle when, in demonstrating a truth, we employ a second truth which cannot be proven without the aid of the first. We are said to beg the question when, in order to establish a proposition, we employ the proposition itself.

ANALYTIC METHOD.—The analytic method begins with the thing required, and by tracing the relations of the various parts we arrive at some known truth. It is a kind of going back from the result sought by a chain of relations to what has been previously established. In a demonstration, we pass through every step from the simplest self-evident truth to the highest deductions of the science; in the process of analysis, we pass over every step from the latter truths down to the simplest.

Analysis is the method of discovery; synthesis, of demonstration. The one has for its object to find unknown truths; the other, to prove known ones. Frequently both methods are employed simultaneously, when the object is to discover new relations, or the solution of new problems; but when we wish to prove to others the truths we have discovered, the synthetical method is usually preferred.

LESSON III.

GEOMETRICAL LANGUAGE.

LANGUAGE is the instrument of thought and the medium of expression. All thinking is by means of language; and the more concise and perfect the language, the more profound and searching is our thought. The language of mathematics differs somewhat from that of ordinary usage, in being more concise and more definite in its use.

Much of the language of mathematics is symbolical; that is, a symbol is used in place of the written word. There are three classes of symbols in Geometry: symbols of quantity, symbols of operation, and symbols of relation.

The SYMBOLS OF QUANTITY are usually pictured representations of the quantities considered. Sometimes, however, the letters of the alphabet are used to indicate them.

The Symbols of Operation are as follow:-

The Sign of Addition, +, called plus; thus, A + B, denotes that B is to be added to A.

The Sign of Subtraction, —, called minus; thus, A - B, denotes that B is to be subtracted from A.

The Sign of Multiplication, \times ; thus, $A \times B$, denotes that A is to be multiplied by B.

The Sign of Division, \div ; thus, $A \div B$, denotes that A is to be divided by B.

The Exponential Sign; thus, A⁴, denotes that A is used four times as a factor, or is raised to the fourth power.

The Radical Sign, $\sqrt{\ }$; thus, $\sqrt{\ }A$, $\sqrt[3]{\ }B$, denotes that the square root of A and the cube root of B are to be extracted.

The Parenthesis and Vinculum denote that the quantity

is to be operated upon as a whole; thus, $(A+B) \times C$, or $\overline{A+B} \times C$, denotes that the sum of A and B is to be multiplied by C.

The Symbols of Relation are as follow:-

The Sign of Equality, =; thus, A = B + C, denotes that A is equal to the sum of B and C.

The expression of the equality of two quantities is an equation; thus, A = B + C, is an equation. The part on the left of the sign of equality is the first member; that on the right is the second member.

The Sign of Inequality, > or <; thus, A > B, denotes that A is greater than B. The greater quantity is at the opening of the sign.

The Sign of Ratio, :; thus, A:B, denotes the ratio of A to B.

The Sign of Equal Ratios, ::; thus, A:B::C:D, denotes that the ratio of A to B equals the ratio of C to D.

We present also a few combinations of these symbols, called *formulas*, which will be found valuable in some of the demonstrations.

1.
$$A \times B + C \times B = (A + C) \times B$$
.

2.
$$\frac{1}{2}A \times B - \frac{1}{2}B \times C = \frac{1}{2}(A - C) \times B$$
.

3.
$$(A+B)^2 = A^2 + 2A \times B + B^2$$
.

4.
$$(A - B)^2 = A^2 - 2A \times B + B^2$$
.

5.
$$(A + B) \times (A - B) = A^2 - B^2$$
.

DEFINITION OF TERMS

An Axiom is a self-evident truth.

A THEOREM is a truth to be demonstrated.

A Problem is a question to be solved.

A POSTULATE is a problem whose solution is self-evident.

A COROLLARY is an obvious consequence of, or a theorem suggested by, one or more propositions.

A Scholium is a remark upon one or more propositions.

Theorems, Axioms, Problems, and Postulates, are all called *Propositions*.

An Hypothesis is a supposition made in the statement of a proposition, or in its demonstration.

Note.—In making references, A. stands for Axiom; B. for Book; C. for Corollary; D. for Definition; I. for Introduction; Th. for Theorem; P. for Problem; S. for Scholium. In referring to another Book, the number of the book is given; in referring to the same Book, the number of the Book is not given.

UNIVERSIDAD AUTÓNO DIRECCIÓN GENERA

ELEMENTARY GEOMETRY.

BOOK I.

DEFINITIONS.

- 1 GEOMETRY is the science which treats of the properties and relations of geometrical magnitudes.
- 2. A GEOMETRICAL MAGNITUDE is some definite element of space. It is a line, a surface, a volume, or an angle.
- 3. A Point is that which has position, but no magnitude.
- 4. A LINE is that which has length, but no breadth or thickness. Lines are straight or curved.
- 5. A STRAIGHT LINE is one which has the same direction at every point: as, AB.
- 6. A CURVED LINE is one which changes its direction at every point: as, CD.

nt: o b

The word line used alone, means a straight line; the word curve, alone, means a curved line.

- 7. A SURFACE is that which has length and breadth, without thickness. Surfaces are plane or curved.
- 8. A PLANE is a surface such that if any two of its points be joined by a straight line, every part of that line will lie in the surface.

A COROLLARY is an obvious consequence of, or a theorem suggested by, one or more propositions.

A Scholium is a remark upon one or more propositions.

Theorems, Axioms, Problems, and Postulates, are all called *Propositions*.

An Hypothesis is a supposition made in the statement of a proposition, or in its demonstration.

Note.—In making references, A. stands for Axiom; B. for Book; C. for Corollary; D. for Definition; I. for Introduction; Th. for Theorem; P. for Problem; S. for Scholium. In referring to another Book, the number of the book is given; in referring to the same Book, the number of the Book is not given.

UNIVERSIDAD AUTÓNO DIRECCIÓN GENERA

ELEMENTARY GEOMETRY.

BOOK I.

DEFINITIONS.

- 1 GEOMETRY is the science which treats of the properties and relations of geometrical magnitudes.
- 2. A GEOMETRICAL MAGNITUDE is some definite element of space. It is a line, a surface, a volume, or an angle.
- 3. A Point is that which has position, but no magnitude.
- 4. A LINE is that which has length, but no breadth or thickness. Lines are straight or curved.
- 5. A STRAIGHT LINE is one which has the same direction at every point: as, AB.
- 6. A CURVED LINE is one which changes its direction at every point: as, CD.

nt: o b

The word line used alone, means a straight line; the word curve, alone, means a curved line.

- 7. A SURFACE is that which has length and breadth, without thickness. Surfaces are plane or curved.
- 8. A PLANE is a surface such that if any two of its points be joined by a straight line, every part of that line will lie in the surface.

9. A VOLUME is that which has length, breadth, and thickness.

PLANE ANGLES.

10. An ANGLE is the difference of direction, or the divergence, of two lines proceeding from a common point.

The point from which the lines proceed is called the *vertex* of the angle; the lines themselves are the *sides* of the angle.

An angle is named by the letter at the vertex, or by the three letters with the letter at the vertex in the middle. Thus, we say the angle C, or the angle ACB.

11. Adjacent Angles are angles which have a common vertex with a common side between them; thus, ACD and BCD are adjacent angles.

12. A RIGHT ANGLE is an angle formed by one straight line meeting another, making the adjacent angles equal. The first line is then said to be perpendicular to the other.

An Acute Angle is one which is less than a right angle; as, DCB.

Obtuse and acute angles are called oblique angles, in distinction from right angles.

PARALLEL LINES.

14. PARALLEL LINES are those owhich have the same direction; as, A. A. B. and C.D.

When a straight line intersects two parallel straight lines, the angles formed take particular names. Suppose the line EF to intersect the parallels AB and CD; then—

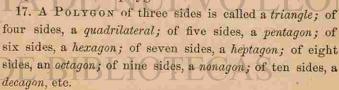

- 1. INTERIOR ANGLES ON THE F
 SAME SIDE are those which lie within the parallels, on
 the same side of the secant, or intersecting line; thus,
 CGH and AHG; also, HGD and GHB;
- 2. ALTERNATE INTERIOR ANGLES lie within the parallels, on different sides of the secant line, but not adjacent; as, CGH and GHB;
- 3. EXTERIOR-INTERIOR ANGLES lie on the same side of the secant line, one without and the other within the parallels, but not adjacent; as EGD and GHB. They are also called *corresponding* angles.

PLANE FIGURES.

15. A PLANE FIGURE is a plane bounded by lines either straight or curved.

16. A POLYGON is a plane figure bounded by straight lines. These lines are called *sides* of the polygon; taken together, they form the *perimeter* of the polygon.

18. An Equilateral Polygon is one whose sides are equal. An Equiangular Polygon is one whose angles are equal.

Two polygons are mutually equilateral when their sides

are respectively equal. Two polygons are mutually equiangular when their angles are respectively equal.

19. A DIAGONAL of a polygon is a line joining the vertices of two angles, not consecutive.

TRIANGLES.

- 20. A TRIANGLE is a polygon of three sides and three angles. Triangles are classified by their sides and their angles.
- 21. A SCALENE TRIANGLE is one in which the three sides are unequal.

22. An Isosceles Triangle is one which has two of its sides equal.

- 23. An Equilateral Triangle is one which has its three sides equal.
- 24. A RIGHT-ANGLED TRIANGLE is one which has one right angle. The side opposite the right angle is called the typothenuse.

26. An OBTUSE-ANGLED TRIANGLE is one which has one obtuse angle.

Triangles are the simplest of all polygons, since three sides are the least number that can bound a plane figure. The properties of polygons are determined by analyzing them into triangles.

QUADRILATERALS.

- 27. A QUADRILATERAL is a polygon of four sides and four angles. There are three classes:—
- 1. The TRAPEZIUM is a quadrilateral having no two sides parallel.

- 3. The Parallelogram is a quadrilateral having its opposite sides parallel.
- 28. Parallelograms are divided, from their angles, into two classes,—right-angled and oblique-angled parallelograms.
- 1. A RECTANGLE is a parallelogram whose angles are right angles.

A SQUARE is an equilateral rectangle.

2. A RHOMBOID is a parallelogram whose angles are oblique.

LEON

A RHOMBUS is an equilateral rhomboid

THE CIRCLE.

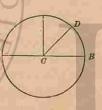

29. A CIRCLE is a plane figure bounded by a curve line, every point of which is equally distant from a point within, called the *centre*.

The CIRCUMFERENCE is the bounding line; any part of the circumference is called an arc. A line through the centre having its ends in the circumference is a diameter; a line from the centre to the circumference is the radius.

30. The arcs of circles are used to measure angles. An angle having its vertex at the centre of a circle is measured by the arc included between its sides; thus, the arc BD measures the angle DCB.

To measure angles, the circumference is divided into 360 equal parts, called degrees. Each degree is divided into 60 equal parts, called minutes; each minute into 60 equal parts, called seconds. Degrees, minutes, and seconds are marked thus, o ' "; 16° 24' 32" are read, 16 degrees, 24 minutes, and 32 seconds.

A right angle, it will be seen, is measured by 90°; half a right angle, by 45°; two right angles, by 180°; four right angles, by 360°.

AXIOMS.

31. An Axiom is a self-evident truth. There are two classes of axioms in Geometry. First, those which pertain to quantity in general; second, those which arise out of the special forms of geometrical quantity.

FIRST CLASS.

- 1. Things which are equal to the same thing are equal to each other.
 - 2. If equals be added to equals, the sums will be equal.

- 3. If equals be subtracted from equals, the remainders will be equal.
- 4. If equals be added to or subtracted from unequals, the results will be unequal.
- 5. If equals be multiplied by equals, the products will be equal.
- 6. If equals be divided by equals, the quotients will be equal.
 - 7. The whole is greater than any of its parts.
 - 8. The whole equals the sum of all its parts.

SECOND CLASS.

- 9. Only one straight line can be drawn connecting two given points.
- 10. A straight line is the shortest distance from one point to another.
 - 11. All right angles are equal to each other.
- 12. Parallel straight lines cannot meet each other when produced.
- 13. Through a given point only one straight line can be drawn parallel to a given line.

Corollary. From axiom 10, it is evident that any side of a triangle is less than the sum of the other two sides.

POSTULATES.

- 32. The following postulates are self-evident problems resulting from the preceding definitions:-
- 1. A straight line can be drawn from one point to another.
- 2. A straight line may be prolonged to any length.
- 3. A line or an angle may be bisected.
- 4. An angle may be described equal to a given angle.

5. A line may be drawn through a given point parallel to a given line.

6. A perpendicular may be drawn to a given line from a point without the line or in the line.

ANALYSIS OF BOOK I .- Book I treats mainly of angles, parallel lines, triangles, and parallelograms. It treats of the angles formed by one line meeting or cutting another, of the angles formed by one line cutting two parallel lines, of the equality and inequality of triangles, of the sum of the angles of a triangle, of the relation of the angles and sides of a parallelogram, and of the exterior and interior angles of a polygon. It is thus seen that the idea of angles is a prominent, if not the principal one of the book.

OF ANGLES.

THEOREM I.

When one straight line meets another straight line, the sum of the two adjacent angles equals two right angles.

Let the straight line DC meet the straight line AB at the point C; then will ACD + DCB =two right angles.

For, at the point C, erect CE perpendicular to AB; then (D. 12,) the angles \overline{A} ACE and ECB are both right angles. Now,

ACD = a right angle + ECD; and

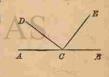

DCB = a right angle - ECD; hence, adding,

we have, ACD + DCB = two right angles.

Therefore, when a straight line meets another straight line, the sum of the two adjacent angles equals two right

Cor. 1. If one of the angles ACD or DCB is a right angle, the other is also a right angle.

Cor. 2. The sum of all the angles formed on the same side of a straight line by drawing lines to any point of that line, is equal to two right angles. For, their sum is equal to the sum of ACD and DCB, A which is equal to two right angles, according to the proposition.

DIRECCIÓN GENERA

THEOREM II.

When two straight lines intersect each other, the opposite or vertical angles are equal.

Let the two straight lines AB and CD intersect each other at the point E; then will $AE\hat{C}$ be equal to BED.

For, since CE meets AB, the angle

AEC + CEB = two right angles (Th. I.); and since BE meets CD, the angle CEB + BED = two right angles; but things which are equal to the same thing are equal to each other (A. 1); hence,

$$AEC + CEB = CEB + BED.$$

Taking from each sum the common angle CEB, there remains (A. 3),

AEC = BED.

In a similar manner it may be shown that the angle AED equals CEB. Therefore, etc.

Cor. 1. The sum of the four angles formed by the intersection of two lines is equal to four right angles.

Cor. 2. The sum of all the angles that can be formed about a point is equal to four right angles.

PARALLEL LINES.

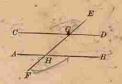

THEOREM III.

If a line intersect two parallel lines;

- 1. The exterior-interior angles will be equal.
- 2. The alternate interior angles will be equal.
- 3. The sum of the interior angles on the same side will be equal to two right angles.

Let the line EF intersect the two parallels AB and CD; then,

First. The angle EGD is equal to GHB. For, since HB and GD are parallel, they have the same direction; Alberto, they must diverge equally from the line EF; therefore, the difference

of direction or divergence of GE and GD must be equal to the divergence of HE and HB, or the angle EGD equal to GHB. In the same way it may be shown that FHB = HGD.

Second. The two alternate angles CGH and EHB will be equal. For, CGH equals EGD (Th. II.); but EGD equals EHB; therefore, CGH = GHB (A. 1); and in the same manner it may be shown that AHG equals HGD.

Third. The sum of the two interior angles GHB and HGD equals two right angles. For, EGD + DGH = two right angles (Th. I.); but EGD = EHB; hence, GHB + HGD = two right angles. In the same way it may be shown that AHG + CGH equals two right angles. Therefore, etc.

Cor. If a line is perpendicular to one of two parallels, it is perpendicular to the other also. For, if EGD were a right angle, its equal EHB would be a right angle also.

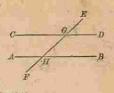

THEOREM IV

Conversely.—If a straight line meets two other straight lines, these two lines will be parallel;

- 1. When the exterior-interior angles are equal.
- 2. When the alternate interior angles are equal.
- 3. When the sum of the two interior angles on the same side is equal to two right angles.

Let the straight line EF meet the two straight lines AB and CD; then,

First. If the angles EGD and EHB are equal, the lines are parallel. For, since EGD and EHB are equal, the lines GD and HB must diverge equally from EF; hence, they have the same direction, and are, therefore, parallel (D. 14).

Second. If the alternate angles CGH and GHB are equal, the lines are parallel. For, since CGH equals EGD (Th. II.), when CGH equals GHB, EGD equals GHB; but then the lines are parallel, as has just been shown; hence, the lines are parallel when the alternate angles are equal.

Third. If the sum of the two interior angles GHB and HGD equals two right angles, the lines are parallel. For, EGD + HGD = two right angles (Th. I.); hence, EGD + HGD = HGD + GHB (A. 1). Taking HGD from each, we have EGD = GHB; but then the lines are parallel, according to the first part of the theorem; hence, they are parallel when GHB + HGD equals two right angles.

Cor. 1. If two lines are perpendicular to the same line, they are parallel. For, if EGD and GHB are both right angles, they are equal, and the lines CD and AB are parallel.

Cor. 2. If two lines are parallel to the same line, they are parallel to each other.

Cor. 3. If the sum of the two interior angles on the same side is less than two right angles, the lines will meet.

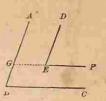

THEOREM V.

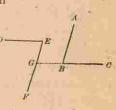

Two angles which have their sides respectively parallel, and lying in the same direction or in opposite directions, are equal.

First. Let the angles ABC and DEF have their sides parallel and lying in the same direction; then will ABC equal DEF. For, prolong FE to G. Then, since AB and

DE are parallel, DEF equals AGE (Th. III.); and since GF and BC are parallel, AGE equals ABC (Th. III.); hence, DEF equals ABC (A. 1).

Second. Let the angles ABC and DEF have their sides parallel and lying in opposite directions; then will ABC equal DEF. For, prolong CB to G. Define ABC equals EGB (Th. III.); but EGB equals DEF, being alternate; hence, ABC equals DEF. Therefore, etc.

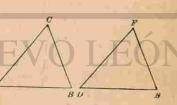

TRIANGLES.

THEOREM VI.

If two triangles have two sides and the included angle of the one equal to two sides and the included angle of the other, each to each, the triangles will be equal in all their parts.

Let the triangles ABC and DEF have the side AB equal to DE, AC to DF, and the angle A equal to the angle D; then will the triangle ABC be equal to the triangle DEF.

For, apply the triangle ABC to the triangle DEF, placing the side AB upon the equal side DE; then, since the angle A equals the angle D, the side AC will take the direction of DF, and the point C will coincide with F, since the two lines are equal; and the side CB will coincide with the side

FE (A. 9). Therefore, the triangles coincide and are equal in all their parts. Therefore, etc.

THEOREM VII.

If two triangles have two angles and the included side of the one equal to two angles and the included side of the other, each to each, the triangles will be equal in all their parts.

Let ABC and DEF be two triangles having the angle A equal to the angle D, the angle B equal to the angle E, and the included side AB equal to the in-

cluded side DE; then will the two triangles be equal in all their parts.

For, apply the triangle ABC to the triangle DEF, placing the side AB upon DE, the point A upon D, and the point B upon E; then, since the angle A equals the angle D, the side AC will take the direction DF, and the point C will be found somewhere in the line DF; and since the angle B equals the angle E, the side BC will take the direction EF, and the point C will be found somewhere in EF. Hence, the point C being in the two lines DF and EF, must be at their intersection; consequently, the triangles coincide and are equal in all their parts. Therefore, etc.

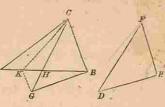

THEOREM VIII.

If two triangles have two sides of the one equal to two sides of the other, each to each, and the included angles unequal, the third side will be greater in the triangle having the greater included angle.

Let ABC and DEF be two triangles in which AC = DF,

BC = EF and ACB > DFE; then will AB be greater than DE.

For, at the point C make the angle BCG = EFD, make CG = FD, and draw BG; then will the triangle AGB equal DFE and GB equal DE (Th. VI.). Draw

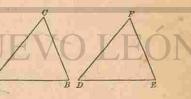

CK, bisecting the angle ACH, and draw also GK; one two triangles ACK and KCG are equal (Th. VI.), and AK = KG. Now, KG + KB > GB; hence AK + KB, or AB, is greater than GB or its equal DE.

The same demonstration will apply when the point G falls within AB. If it falls on AB, the theorem is true by A. 7. Cor. The converse of this theorem is also true.

THEOREM IX.

If two triangles have the three sides of the one equal to the three sides of the other, each to each, the triangles will be equal in all their parts.

Let ABC and DEF be two triangles, having AB equal to DE, AC to DF, and BC to EF; then will the triangles be equal in all their parts.

For, since AC and AB are respectively equal to DF and DE, if the angle A were greater than D, BC would be greater than EF (Th. VIII.); and if A were less than D, BC would be less than EF, for the same reason. But BC is equal to EF, therefore the angle A must be equal to D.

In the same way it may be shown that the angle C equals F, and the angle B equals E. Therefore, etc.

THEOREM X.

In an isosceles triangle the angles opposite the equal sides are equal.

Let ABC be an isosceles triangle, having the side AC equal to the side BC; then will the angle A be equal to the angle B.

Join the vertex C and the middle point of A between the base AB; then in the two triangles ADC and CDB, AC equals BC, DC is common, and AD equals DB; hence, the two triangles are equal in all their parts (Th. IX.), and the angle A is equal to the angle B.

Cor. 1. A line drawn from the vertex of an isosceles triangle to the middle point of the base, bisects the vertical angle and is perpendicular to the base; also, a line bisecting the vertical angle is perpendicular to the base and bisects it; also, a line drawn from the vertex perpendicular to the base bisects both the base and the vertical angle.

Cor. 2. Hence, also, an equilateral triangle is equiangular; that is, it has all its angles equal.

THEOREM XI.

Conversely.—If two angles of a triangle are equal, the side opposite them are also equal, and the triangle is isosceles.

Let ABC be a triangle, having the angle A equal to the angle B; then will the side AC be equal to BC.

For, if AC and CB are not equal, suppose one of them, as AC, to be the greater. Then, take AD equal to BC, and draw DB.

Now, in the triangles ABC and ABD, we have the side AD

equal to BC, by construction, the side AB common, and the included angle ABC equal to the included angle DAB, by hypothesis; hence, the two triangles ABD and ABC are equal (Th. VI.); that is, a part is equal to the whole, which is impossible (A. 7). Hence, AC cannot be greater than BC; in the same way it may be shown that AC cannot be less than BC; hence, AC and BC are equal, and the triangle is isosceles. Therefore, etc.

THEOREM XII.

In any triangle the greater side is opposite the greater angle, and, conversely, the greater angle is opposite the greater side.

In the triangle ABC, let the angle ABC be greater than CAB; then will AC be greater than BC.

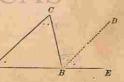

For, draw BD, making the angle ABD = DAB; then will AD = DB (Th. XI.). To ABB each add DC and we have AD + DC = DB + DC; but DB + DC > BC (A. 10); hence, AD + DC, or AC, is greater than BC.

Conversely. Let the side AC > BC; then will the angle ABC > CAB. For, if ABC < CAB, AC < BC, from what has just been proved; and if ABC = CAB, AC = BC (Th. XI.); but both of these results are contrary to the hypothesis; hence, ABC must be greater than CAB. Therefore, etc.

THEOREM XIII.

In every triangle the sum of the three angles is equal to two right angles.

Let ABC be a triangle; then will the sum of its three angles, A, B, C, be equal to two right angles. For, prolong AB, and draw BD

parallel to AC; then, since the parallels AC and BD are cut by AE, the angle A is equal to the opposite exterior angle DBE (Th. III.). In like manner, since the parallels are gut by BC, the alternate angles C and CBD are equal; acree, the sum of the three angles of the triangle is equal to the sum of the angles ABC, CBD, DBE; but this latter sum equals two right angles (Th. I. C. 2); therefore, the sum of the three angles of the triangle equals two right angles. Therefore, etc.

Cor. 1. If two angles of a triangle are given, the third will be found by subtracting their sum from two right angles, or 180°; hence, if two triangles have two angles of the one equal to two angles of the other, the third angles will be equal.

Cor. 2. A triangle cannot have more than one right angle; for if there were two the third angle would be zero.

Cor. 3. A triangle can have only one obtuse angle, but must have at least two acute angles.

Cor. 4. In a right-angled triangle the sum of the two acute angles equals one right angle, or 90°.

Cor. 5. In every triangle the exterior angle is equal to the sum of the two interior opposite angles.

Scholium. This theorem may be demonstrated by drawing a line parallel to either of the other sides of the triangle. Let the pupils be required to do it.

THEOREM XIV.

If from a point without a straight line a perpendicular be let fall on the line and oblique lines be drawn;

- 1. The perpendicular will be shorter than any oblique line.
- 2. Any two oblique lines which terminate at equal distances from the foot of the perpendicular are equal.
- 3. The oblique line which terminates at the greater distance from the foot of the perpendicular is the greater.

Let C be a given point, and AD a given line, CE a perpendicular, and CA, CB, and CD, oblique lines; then,

First. In the triangle AEC, the angle AEC is a right angle, and, consequently, greater than A; therefore, the side CE is shorter than CA (Th. XII.).

Second. Let AE = EB; then, since CE is common and the angle AEC = CEB, the triangles AEC and CEB are equal (Th. VI.), and AC equals BC.

Third. Let ED be greater than EB; then, since CBE is an acute angle, CBD must be obtuse and BDC acute, and in the triangle CBD; CD is greater than BC, being opposite the greater angle (Th. XII.). Therefore, etc.

Cor. 1. Only one perpendicular can be drawn from the same point to the same straight line.

Cor. 2. Two equal oblique lines terminate at equal distances from the foot of the perpendicular.

Cor. 3. A line having two points, each equally distant from the extremities of another line, is perpendicular to that line and bisects it.

OUADRILATERALS.

In any parallelogram, the opposite sides and angles are equal. each to each.

Let ABCD be a parallelogram; then will AB be equal to DC, and AD to BC.

For, draw the diagonal DB. Then, since AB and DC are parallel, the alternate angles ABD and BDC are equal (Th. III.); and since AD and

BC are parallel, the alternate angles ADB and DBC are equal. Hence, the two triangles ABD and DBC have two angles and the included side, DB, of one, equal to two angles and the included side, DB, of the other, each to each; therefore, the triangles are equal (Th. VII.); and the side AB opposite the angle ADB is equal to the side DC opposite the equal angle DBC: hence, also, the side AD equals BC; therefore, the opposite sides of a parallel-ogram are equal.

Again, since the triangles are equal, the angle A is equal to the angle C; and the angle ADC, which is made up of the two angles ADB and BDC, is equal to the angle ABC, which is made up of the equal angles DBC and ABD. Therefore, etc.

Cor. 1. The diagonal divides the parallelogram into two equal triangles.

Cor. 2. Two parallels included between two other parallels are equal.

Cor. 3. Two parallelograms are equal when they have two sides and the included angle of one, equal to two sides and included angle of the other.

THEOREM XVI.

If the opposite sides of a quadrilateral are equal, each to each, the equal sides are parallel, and the figure is a parallelogram.

Let ABCD be a quadrilateral, in which AB equals DC, and AD equals BC; then will it be a parallelogram.

For, draw the diagonal DB. Then the triangles ABD and DBC have all the sides of the one equal to all the sides of the other, each to each; therefore the two triangles are equal (Th. IX.); and the

angle ABD opposite the side AD is equal to the angle BDC opposite the equal side BC; therefore, the side AB is parallel to the side DC (Th. IV.). For a like reason, AD is parallel to BC; therefore, the figure ABCD is a parallelogram. Therefore, etc.

THEOREM XVII.

If two sides of a quadrilateral are equal and parallel, the figure is a parallelogram.

Let ABCD be a quadrilateral, having the sides AB and DC equal and parallel; then will ABCD be a parallelogram.

For, draw the diagonal DB. Then, since AB is parallel to DC, the alternate angles ABD and BDC are equal (Th. III.). Now, the triangles ABD and DBC have the side AB equal to DC, by hypothesis, the side DB common, and the included angles ABD and BDC equal; hence, the triangles are equal (Th. VI.), and the alternate angles ADB and DBC are equal; hence, the sides AD and BC are parallel (Th. IV.), and the figure

THEOREM XVIII.

The diagonals of a parallelogram bisect each other; that is, divide each other into equal parts.

Let ABCD be a parallelogram, and AC and DB its diagonals; then will AE be equal to EC, and DE to EB.

is a parallelogram. Therefore, etc.

For, since AB and DC are parallel, the A B angle CDE equals ABE (Th. III.); and also DCE equals EAB; and since AB equals DC, the triangles AEB and DEC have two angles and the included side of the one

equal to two angles and the included side of the other, hence, the triangles are equal (Th. VII.), AE equals CE, and DE equals BE; therefore, the diagonals are bisected at E.

ANGLES OF POLYGONS.

THEOREM XIX.

If each side of a convex polygon be produced so as to form one exterior angle at each vertex, the sum of the exterior angles will be equal to four right angles.

Let ABCDEF be a convex polygon, with each side produced so as to form one exterior angle at each vertex; then will the sum of the exterior angles be equal to four right angles.

For, from any point within the polygon, draw lines respectively parallel to the sides of the polygon; the angles contained by the

lines about this point will be equal to the exterior angles of the polygon (Th. V.). But the sum of the angles formed about a point equals four right angles (Th. II. C. 2); hence, the sum of the exterior angles of a polygon equals four right angles. Therefore, etc.

Cor. 1. The sum of the interior angles of a polygon is equal to twice as many right angles as the polygon has sides, less four right angles.

The sum of each exterior and interior angle equals two right angles, and there are as many of each as the polygon has sides; hence, the sum of all the exterior and interior angles equals two right angles taken as many times as there are sides of the polygon. But the sum of the exterior angles equals

four right angles; hence, the sum of the interior angles equals two right angles taken as many times as the polygon has sides, minus four right angles.

Cor. 2. The sum of the interior angles of a quadrilateral equals 2 right angles multiplied by 4, minus 4 right angles, which is 8 - 4, or 4 right angles. In a rectangle each angle is a right angle.

Cor. 3. The sum of the angles of a pentagon equals $2 \times$ 5-4=6 right angles. Each angle of an equiangular pentagon is $\frac{1}{5}$ of 6 or $\frac{6}{5}$ of a right angle, or 108°.

Cor. 4. The sum of the angles of a hexagon equals 2 X 6-4=8 right angles. Each angle of an equiangular hexagon is 4 of a right angle, or 120°.

Cor. 5. In polygons of the same number of sides, the sum of the angles is the same. In equiangular polygons, each angle equals the sum divided by the number of sides.

Scholium. This theorem is true at whichever extremity the sides are produced.

PRACTICAL EXAMPLES.

A common deficiency of pupils in the study of Geometry, is their inability to make a practical application of their knowledge. To remedy this, practical examples should be given, either in connection with the theorems or at the close of each book. The following problems may be used in either of these ways which the teacher may prefer.

1. If one line meet another line at an angle of 60°, what is the value of the adjacent angle?

SOLUTION. If the line DC meets AB, making the angle DUB equal to 60°, the angle ACD will equal 180° - 60°, or 120°, since ACD+DCB=180°.

2. If two lines meet a third at the same point, making angles equal to 30° and 80° respectively, required the angle between the two lines.

- 3. How many degrees in each angle of a rectangle?
- 4. How many degrees in each angle of an equilateral triangle?
- 5. If two angles of a triangle are 43° and 75° respectively, what is the other angle?
- 6. If two angles of a triangle are each 45°, what is the other angle, and what is the kind of triangle?
- 7. If one angle of a triangle is 60°, what is each of the other two, if equal, and what is the kind of triangle?
- 8. If one of the two equal angles of a triangle is 30°, what is each of the other angles?
- 9. Required the number of degrees in each angle of an equiangular pentagon.
- 10. Required the number of degrees in each angle of an equiangular hexagon.
- 11. In a triangle whose angles are A, B, C, what is each angle if A is twice and B three times C?
- 12. In the preceding problem, what is the kind of triangle?
- 13. Required each angle of an isosceles triangle, if the unequal angle equals twice the sum of the other two.
- 14. Required the value of each exterior angle of an equiangular octagon.

EXERCISES FOR ORIGINAL THOUGHT.

We now give some theorems to exercise the pupil in original thought. The importance of such exercises cannot be overestimated. Much of the discipline of Geometry is lost by the pupil memorizing the demonstrations given in the book. One can become a good geometer only by trying his powers with new theorems and problems, and endeavoring to find out demonstrations and solutions for himself.

These theorems may be given upon review, one of them in connection with the regular lesson; or, if the teacher prefer, the lesson may consist wholly of them. With classes whose time for the study is limited, they may be omitted.

1. If the equal sides of an isosceles triangle be produced, the two obtuse angles below the base will be equal.

- If the three sides of an equilateral triangle be produced, all the external acute angles will be equal, and all the obtuse angles will be equal.
- 3. Either side of a triangle is greater than the difference between the other two.
- 4. If a line be drawn bisecting an angle, any point of the bisecting line is equally distant from the sides of the angle.
- . 5. Prove that the diagonals of a rectangle are equal.
- If the diagonals of a quadrilateral bisect each other at right angles, the figure is a rhombus or square.
- 7. If a line joining two parallels be bisected, any other line through the point of bisection and joining the two parallels, is also bisected at that point.
- 8. If from any point within a triangle, two straight lines be drawn to the extremities of any side, their sum will be less than the sum of the other two sides of the triangle.
- 9. If a line is perpendicular to another line at its middle point,—
 1. Any point in the perpendicular will be equally distant from the extremities. 2. Any point out of the perpendicular will be unequally distant from the extremities.

RATIO AND PROPORTION.

- 1. All reasoning is by comparison. In comparing two quantities, we see that they bear a certain relation to each other.
- 2. RATIO is the measure of the relation of two similar quantities. It is found by dividing the first by the second; thus, the ratio of 8 to 4 is $\frac{8}{4}$, or 2, the ratio of A to B is $\frac{A}{B}$
- 3. The two quantities compared are called the *Terms* of the ratio. The first is called the *Antecedent*, the second the *Consequent*, and the two constitute a *Couplet*.
- 4. A ratio is indicated by placing a colon between the quantities, or by writing the consequent under the antecedent, as in division; thus, the ratio of A to B is written.

$A: B, \text{ or } \frac{A}{B}$.

- 5. A Proportion is an expression of equality between equal ratios; thus, the ratio of 8 to 4 equals the ratio of 6 to 3, and a formal comparison of these, as 8:4=6:3, is a proportion.
- 6. The equality of ratios is usually indicated by a double colon; thus, 8:4::6:3. This is read, the ratio of 8 to 4 equals the ratio of 6 to 3, or, 8 is to 4 as 6 is to 3.
- 7. There are four terms in a proportion; the first and fourth are called the extremes; the second and third, the

means. The first and second together are the first couplet; the third and fourth, the second couplet.

- 8. Quantities are in proportion by Alternation, when antecedent is compared with antecedent, and consequent with consequent; thus, if A:B::C:D, by alternation we have 4:C::B:D.
- 9. Quantities are in proportion by *Inversion*, when the antecedents are made consequents and the consequents antecedents; thus, if A:B::C:D, by inversion we have B:A::D:C.
- 10. Quantities are in proportion by Composition, when the sum of antecedent and consequent is compared with either antecedent or consequent; thus, if A:B::C:D, by composition we have, A:A+B::C:C+D.
- 11. Quantities are in proportion by Division, when the difference of antecedent and consequent is compared with either antecedent or consequent; thus, if A:B::C:D, we have, A:A-B::C:C-D.

A CONTINUED PROPORTION is a series of equal ratios; as, A:B::C:D::E:F::, etc.

ANALYSIS.—The object of the theorems of this book is to derive the principles of proportion. These principles are employed in the books which follow. The method consists in regarding a proportion as an equation, which it really is,—an equality of ratios. Thus, the pupil should be taught to regard the proportion A:B::C:D as equivalent to $A \div B = C \div D$, and as soon as this idea is clearly fixed in the mind the subject becomes simple and easy. The first proportion is the basis of demonstration for the others, and may be used as a test of the truth of all others.

THEOREM I.

If four quantities are in proportion, the product of the means will equal the product of the extremes.

Take the proportion

A:B::C:D; then we wish to prove

that $A \times D = B \times C$.

For, from the proportion we have

 $\frac{A}{B} = \frac{C}{D}$; multiplying by $B \times D$,

we have, $A \times D = B \times C$.

Therefore, if four quantities are, etc.

THEOREM II.

If the product of two quantities equals the product of two other quantities, the quantities forming one product may be made the means, and the other two the extremes of a proportion.

Suppose we have

 $A \times D = B \times C$; dividing by $B \times D$,

we have, $\frac{A}{R} = \frac{C}{D}$; placing this in another form,

we have, A: B:: C: D.

Therefore, etc.

THEOREM III.

A mean proportional between two quantities equals the square root of their product.

Let B be a mean proportional between A and C; then we have,

whence (Th. I.), $B^2 = A \times C$

 $B = \sqrt{A \times C}$.

Therefore, etc.

THEOREM IV.

If four quantities are in proportion, they will be in proportion by alternation.

A:B::C:D; from this (Th. I.) Suppose

 $A \times D = B \times C$; dividing by $D \times C$, we have,

 $\frac{A}{C} = \frac{B}{D}$; whence, we have,

A:C::B:D.

Therefore, etc.

REMARK .- The proposition is evidently true, since we have the same products when we take the product of the means and extremes as before the change. This principle may be applied to several other propositions.

THEOREM V.

If four quantities are in proportion, they will be in proportion by inversion.

A:B::C:D; from this Suppose

 $\frac{A}{R} = \frac{C}{D}$; taking the reciprocal, we have.

 $\frac{B}{A} = \frac{D}{C}$; whence, we have,

B:A::D:C.

If four quantities are in proportion, they will be in proportion by composition.

Suppose A:B:C:D; then A we have, $\frac{A}{B} = \frac{C}{D}$. Adding one to each

we have, $\frac{A}{R} + 1 = \frac{C}{D} + 1$; reducing to a common denomi-

nator, we have, $\frac{A+B}{B} = \frac{C+D}{D}$; whence, A+B:B::C+D:D.

Therefore, etc.

THEOREM VII.

If four quantities are in proportion, they will be in proport a by division.

Suppose A: B: C: D; then we have, $\frac{A}{B} = \frac{C}{D}$; subtracting 1, we have, $\frac{A}{B} - 1 = \frac{C}{D} - 1$; reducing,

we have, A - B = C - D; whence,

A = B : B :: C = D : D.

Therefore, etc.

THEOREM VIII.

If two proportions have a couplet in each the same, the other couplets will form a proportion.

Suppose A:B::C:D; and A:B::E:F; then,

 $\frac{A}{B} = \frac{C}{D}$ and $\frac{A}{B} = \frac{E}{F}$; hence (A. 1),

 $\frac{C}{D} = \frac{E}{F}$; whence C: D: :E: F.

Cor. If two proportions have a couplet in each proportional, the other couplets will form a proportion.

THEOREM IX.

Equimultiples of two quantities are proportional to the quantities themselves.

Let A and B be any two quantities; then

 $\frac{A}{B} = \frac{A}{B}$; multiply both terms of the first by m_i

we have, $\frac{mA}{mB} = \frac{A}{B}$; whence, mA: mB: A: B.

Therefore, etc.

THEOREM X.

If four quantities are in proportion, any equimultiples of the first couplet will be proportional to any equimultiples of the second couplet.

Suppose A:B::C:D; then $\frac{A}{B}=\frac{C}{D};$ hence, also,

we have, $\frac{mA}{mB} = \frac{nC}{nD}$; whence

we have, $mA: mB:: nC: nD. \supseteq \emptyset$

Therefore, etc.

THEOREM XI.

The products of the corresponding terms of two or more proportions are proportional.

Suppose A:B::C:D, and M:N::P:Q; then

 $A \times D = B \times C$

 $M \times Q = N \times P$; taking their product,

we have,

we have,

 $A \times M \times D \times Q = B \times N \times C \times P$; whence (Th. II.) we have, $A \times M : B \times N : C \times P : D \times Q$.

 $\times M: B \times N:: C \times P: D \times Q$

THEOREM XII.

In any continued proportion, any antecedent will be to its consequent as the sum of the antecedents is to the sum of the consequents.

Let A:B:

A:B::C:D::E:F, etc.

Then, since A:B::C:D, and

A:B::E:F; we have

 $A \times D = B \times C$, and $A \times F = B \times E$; adding

to these, $A \times B = A \times B$, we have,

 $A \times B + A \times D + A \times F = A \times B + B \times C + B \times E$

or, $A \times (B+D+F) = B(A+C+E);$

whence, A:B::A+C+E:B+D+F.

PRACTICAL EXERCISES.

- 1. If the first three terms of a proportion are 12, 14, and 18, what is the fourth term?

 Ans. 21.
- 2. Given the proportion 3:12::5:20; what proportion have we by composition?
- 3. Find a mean proportional to 12 and 27; to m and n.

Ans. 18; $\sqrt{m} \times n$.

4. If the ratio of A to B is 4, what is the ratio of 3 A to 2 B?

Ans. 2.

5. If the ratio of 3 A to 2 B is 3, what is the ratio of A to B?

Ans. 1.

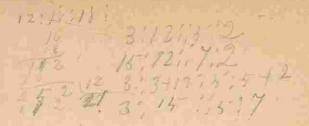

6. What proportion is deducible from the equation $M \times N = A^2 - B^2$

Ans. M: A + B: A - B: N.

7. What proportion is deducible from the equation $(C+D) \times A = (A+B) \times C^{g}$ Ans. A:B::C:D

THEOREMS FOR ORIGINAL THOUGHT.

- 1. If a:b::c:d, prove that am:bn::cm:dn.
- 2. If a:b::c:d, prove that $\frac{a}{m}:\frac{b}{n}::\frac{c}{m}:\frac{d}{n}$.
- 3. If a:b::c:d, prove that a:a+b::c:c+d.
- 4. If a:b::c:d, prove that a+b:a-b::c+d:c-c
- 5. If a:b::c:d and m:c::n:d, prove that a:b::m:n.

BOOK III.

AREAS AND RELATIONS OF POLYGONS.

- 1. This book treats of the area of polygons and their relation to each other.
- 2. The Area of a polygon is its quantity of surface: it is expressed by the number of times which the polygon contains some other area assumed as a *unit of measure*.
- 3. The ALTITUDE OF A TRIANGLE is the perpendicular distance from the vertex of either angle to the opposite side, or the opposite side produced.

The vertex of the angle from which the altitude is drawn is called the vertex of the Triangle; the opposite side is called the base of the triangle.

4. The ALTITUDE OF A PARALLELOGRAM is the perpendicular distance between two opposite sides.

These opposite sides are called bases, one is the upper base, the other the lower base.

5. The ALTITUDE OF A TRAPEZOID is the perpendicular distance between its parallel sides.

6. SIMILAR POLYGONS are those which are mutually equiangular, and in which the corresponding sides are proportional.

A:B::E:F; we have

 $A \times D = B \times C$, and $A \times F = B \times E$; adding

to these, $A \times B = A \times B$, we have,

 $A \times B + A \times D + A \times F = A \times B + B \times C + B \times E$

or, $A \times (B+D+F) = B(A+C+E);$

whence, A:B::A+C+E:B+D+F.

PRACTICAL EXERCISES.

- 1. If the first three terms of a proportion are 12, 14, and 18, what is the fourth term?

 Ans. 21.
- 2. Given the proportion 3:12::5:20; what proportion have we by composition?
- 3. Find a mean proportional to 12 and 27; to m and n.

Ans. 18; $\sqrt{m} \times n$.

4. If the ratio of A to B is 4, what is the ratio of 3 A to 2 B?

Ans. 2.

5. If the ratio of 3 A to 2 B is 3, what is the ratio of A to B?

Ans. 1.

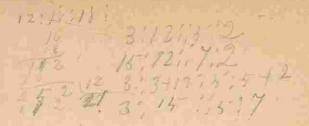

6. What proportion is deducible from the equation $M \times N = A^2 - B^2$

Ans. M: A + B: A - B: N.

7. What proportion is deducible from the equation $(C+D) \times A = (A+B) \times C^{g}$ Ans. A:B::C:D

THEOREMS FOR ORIGINAL THOUGHT.

- 1. If a:b::c:d, prove that am:bn::cm:dn.
- 2. If a:b::c:d, prove that $\frac{a}{m}:\frac{b}{n}::\frac{c}{m}:\frac{d}{n}$.
- 3. If a:b::c:d, prove that a:a+b::c:c+d.
- 4. If a:b::c:d, prove that a+b:a-b::c+d:c-c
- 5. If a:b::c:d and m:c::n:d, prove that a:b::m:n.

BOOK III.

AREAS AND RELATIONS OF POLYGONS.

- 1. This book treats of the area of polygons and their relation to each other.
- 2. The Area of a polygon is its quantity of surface: it is expressed by the number of times which the polygon contains some other area assumed as a *unit of measure*.
- 3. The ALTITUDE OF A TRIANGLE is the perpendicular distance from the vertex of either angle to the opposite side, or the opposite side produced.

The vertex of the angle from which the altitude is drawn is called the vertex of the Triangle; the opposite side is called the base of the triangle.

4. The ALTITUDE OF A PARALLELOGRAM is the perpendicular distance between two opposite sides.

These opposite sides are called bases, one is the upper base, the other the lower base.

5. The ALTITUDE OF A TRAPEZOID is the perpendicular distance between its parallel sides.

6. SIMILAR POLYGONS are those which are mutually equiangular, and in which the corresponding sides are proportional.

Corresponding sides or angles are those which are like placed. They are sometimes called homologous.

7. EQUIVALENT POLYGONS are those which are equal in area. Polygons which, being applied to each other, coincide throughout their whole extent, are said to be equal in all their parts, or simply equal.

The term equal is often used in geometry for equivalent, meaning equal in area. The sign of equality, =, is used in comparing equivalent figures, and is read "equals," or "is equal to."

8. A REGULAR POLYGON is a polygon which is both equilateral and equiangular.

ANALYSIS.—The first object of this book is to find the area of polygons. It begins with the area of a rectangle, assuming as a unit of measure a square whose side is a measure of the sides of the given rectangle. From the area of the rectangle we pass to the area of any parallelogram, thence to the area of a triangle, and from this to the area of any plane figure.

The book also treats of the relations of the squares on the sides of triangles, and the relation of the angles, sides, and area of similar polygons, to each other. It is one of the most interesting and practical books of Geometry.

UNIVERSIDAD AUTO

DIRECCIÓN GENERA

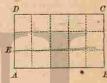

AREA OF POLYGONS.

THEOREM I.

The area of a rectangle is equal to the product of its base and altitude.

Let ABCD be a rectangle; then will its area be equal to the product of its base and altitude.

For, let the line AE be a unit of measure of the base and altitude, and suppose it contained any number as 5 times in the base and 3 times in the altitude; then, divide AB into 5 equal

parts and AD into 3 equal parts, and through the points of division draw lines parallel, respectively, to the sides AB and AD; then will the rectangle be divided into equal squares. For, their sides are equal (B. I. Th. XV. C. 2); their angles are right (B. I. Th. III.); hence, the figures are equal squares (B. I. Th. XV. C. 3).

Now, the whole number of these squares is equal to the number in one row multiplied by the number of rows, which is the same as the number of linear units in the base multiplied by the number of linear units in the altitude; and the same is evidently true for any other numbers than 3 and 5. Hence, the area of ABCD equals $AB \times AD$.

Since this is true when the linear unit of measure is any length, it is true when it becomes exceedingly small, and is, therefore, true when it becomes infinitely small, as it must when the two sides are incommensurable. There

BOOK III.

57

fore, the area of a rectangle is equal to the product of its base and altitude.

Cor. 1. Rectangles are to each other as the products of their bases and altitudes. For, let AB and AD represent the base and altitude of one rectangle, and EF and EH the base and altitude of another; then we will have the identical proportion, $ABCD: EFGH: AB \times AD: EF \times EH$.

Cor. 2. Rectangles having equal bases are to each other as their altitudes. For, suppose the bases AB and EF equal; then, cancelling the equal factor in the second couplet, we have, ABCD: EFGH: AD: EH.

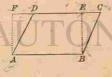

Cor. 3. Rectangles having equal altitudes are to each other as their bases. For, suppose the altitudes AD and EH are equal; then, by cancelling the equal factor in the second couplet of Cor. 1, we have, ABCD: EFGH:: AB: EF.

THEOREM II.

The area of a parallelogram is equal to the product of its base and altitude.

Let ABCD be a parallelogram, AB its base, and EB its altitude; then will its area be equal to $AB \times EB$.

For, at the points A and B draw the two perpendiculars AF and BE, and complete the rectangle ABEF. Then, the angle ADF equals the angle BCE, and

FAD equals CBE (B. I. Th. V.); hence, the two triangles are equal (B. I. Th. VII.); therefore, ABED + BCE is equal to ABED + ADF, or the parallelogram ABCD is equal to the rectangle ABEF. But the area of the rectangle is equal to $AB \times BE$; hence, the area of the parallelogram is equal to $AB \times BE$. Therefore, etc.

Cor. 1. Parallelograms are to each other as the products of their bases and altitudes.

Cor. 2. Parallelograms having equal altitudes are to each other as their bases; and parallelograms having equal bases are to each other as their altitudes.

THEOREM III.

The area of a triangle is equal to half the product of its base and altitude.

Let ABC be a triangle, AB its base, and CD its altitude; then will its area be equal to half the product of its base and altitude.

For, draw BE parallel to AC, and CE parallel to AB, completing the parallelogram ABEC; then will the triangle ABC be one-half the parallelogram ABEC (B. I. Th. XV. C. 1).

Cor. 1. Triangles are to each other as the products of their bases and altitudes.

Cor. 2. Triangles having equal altitudes are as their bases; having equal bases, they are as their altitudes.

THEOREM IV.

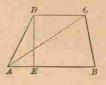

The area of a trapezoid is equal to one-half the sum of the parallel sides multiplied by the altitude.

Let ABCD be a trapezoid, AB and DC its parallel sides, and DE its altitude; then will its area equal $\frac{1}{2}(AB + DC) \times DE$.

BUOK III.

59

For, draw the diagonal AC, dividing the trapezoid into the two triangles ABC and ADC, the altitude of each being DE. The area of ABC is $\frac{1}{2}AB \times DE$, the area of ADC is $\frac{1}{2}DC \times DE$; hence, the area of ABCD, the sum of these triangles, is

 $\frac{1}{2}$ $AB \times DE$ plus $\frac{1}{2}$ $DC \times DE$, which is $\frac{1}{2}$ $(AB + DC) \times DE$. Therefore, etc.

SQUARES ON LINES.

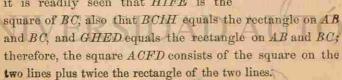

THEOREM V.

The square described on the sum of any two lines is equal to the sum of the squares described on the lines, plus twice the rectangle of the lines.

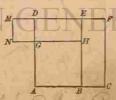

Let AB and BC be two lines, and AC their sum; then will

 $\overline{AC^2} = \overline{AB^2} + \overline{BC^2} + 2 \overline{AB} \times BC.$

For, on AC construct the square ACFD and on AB construct the square ABHG; prolong BH to E and GH to L. Now, it is readily seen that HIFE is the

Cor. 1. The square of the difference of two lines equals the sum of the squares of the lines, minus twice the rectangle of the lines. For, construct a square on AC and on AB, prolong BH to E and HG to N, making GN = BC, and con-

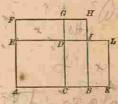

struct the square GM; then the rectangles BF and HM are each equal to $AC \times BC$. Now, ACFD + NGDM - BCFE - HEMN = ABHG; or,

 $\overline{AC^2} + \overline{BC^2} - 2AC \times BC = \overline{AB^2}$.

Cor. 2. The rectangle contained by the sum and difference of two lines equals the difference of their squares. For, construct a

square on AB and on AC, take BK = BC, and construct the rectangle AL; then AK = AB + BC, AC = AB - BC, BKLI = DGFE, and AKLE = (AB + BC) (AB - BC). Now, AKLE = ABIE + DF, which equals ABHF = DIHG; hence,

 $(AB + BC)(AB - BC) = \overline{AB^2} - \overline{BC^2}.$ THEOREM VI.

The square described on the hypothenuse of a right-angled triangle is equal to the sum of the squares described on the other two sides.

Let ABC be a triangle, right-angled at B; then will $\overline{AC^2} = \overline{AB^2} + \overline{BC^2}$.

For, construct squares on each of the sides, draw BD parallel to AF and produce it to E, and draw B the diagonals BF and HC. The two triangles HAC and BAF are equal; for, AC equals AF, being sides of the same square, HA equals AB, for the same reason, and the angle HAC equals the

The triangle BAF is one-half of the rectangle AFED, since it has the same base and the same altitude (Th. III.);

also, since IBC is a straight line, the triangle HAC and square ABIH have the same altitude; hence, the triangle is one-half of the square (Th. III.). But these two triangles BAF and HAC are equal; hence, the rectangle AFED is equal to the square ABIH. In the same manner we may prove that the rectangle EGCD is equal to the square BCLK; hence, the sum of the two rectangles, or the square on AC is equal to the sum of the two squares HB and BL. Therefore, etc.

Cor. 1. The square of either side about the right angle is equal to the square of the hypothenuse diminished by the square of the other side.

For, since $\overline{AB^2} + \overline{BC^2} = AC^2$, we have, by transposing, $\overline{AB^2} = \overline{AC^2} - \overline{BC^2}$.

Cor. 2. The square of the diagonal of a square is equal to twice the square of the side of the square.

Let ABCD be a square, then will $\overline{AC^2}$ $2\overline{AB^2}$. For, we have, by the theorem, $\overline{AC^2}$ $\overline{AB^2} + \overline{BC^2}$; but $\overline{AB^2}$ equals $\overline{BC^2}$; hence, by substitution, we have $AC^2 = A\overline{B^2} + \overline{AB^2}$, or, $\overline{AC^2} = 2\overline{AB^2}$.

Cor. 3. The side of a square is to its diagonal as 1 is to the square root of 2.

For, since $2\overline{AB^2} = \overline{AC^2}$, or, $2 \times \overline{AB^2} = \overline{AC^2} \times 1$, we have the proportion (B. II. Th. II.),

 $AB^2:AC^2::1:2$; extracting the square root,

we have, AB: AC::1:1/2.

Cor. 4. Two right-angled triangles are equal in all their parts when they have two corresponding sides respectively equal.

Note.-This is the celebrated Pythagorean proposition, so called because it was discovered by Pythagoras. It is also known as the 47th of Euclid. that being its number in the first book of Euclid's Elements.

THEOREM VII.

In any obtuse-angled triangle, the square of the side opposite the obtuse angle is equal to the sum of the squares of the other two sides, plus twice the product of the base into the distance from the vertex of the obtuse angle to the foot of the perpendicular drawn from the vertex of the angle opposite the base to the base produced.

Let ABC be a triangle, of which A is an obtuse angle, AB its base, and CD the perpendicular drawn to the base produced; then will

$$\overline{BC^2} = \overline{AC^2} + \overline{AB^2} + 2AB \times ADD$$

For, in the right-angled triangle DBC, we have, $\overline{BC^2} = \overline{DC^2} + \overline{DB^2}$;

 $DB = AB + AD; = \cdots$ but

hence, $\overline{DB^2} = \overline{AB^2} + \overline{AD^2} + 2\overline{AB} \times AD$ (Th. V.).

Hence, $\overline{BC^2} = \overline{DC^2} + \overline{AB^2} + \overline{AD^2} + 2\overline{AB} \times AD$.

 $\overline{DC^2} + \overline{AD^2} = \overline{AC^2}$ But.

Hence, $BC^2 = \overline{AB^2} + \overline{AC^2} + 2AB \times AD$.

化平日 化产生见到了

Cor. 1. If the angle CAB becomes a right angle, AL becomes zero, and we have, $\overline{BC^2} = \overline{AB^2} + \overline{AC^2}$.

THEOREM VIII.

In any triangle, the square of a side opposite an acute angle is equal to the sum of the squares of the other two sides, minus twice the product of the base and the distance from the vertex of the acute angle to the foot of the perpendicular let fall upon the base or the base produced.

Let ABC be any triangle, B an acute angle, AB its base, and CD the perpendicular; then will

$$AC^2 = \overline{AB^2} + \overline{BC^2} - 2AB \times BD.$$

For, in the right-angled triangle ADC,

we have, $\overline{AC^2} = \overline{DC^2} + \overline{AD^2}$;

but AD = AB - DB;

hence, $\overline{AD^2} = \overline{AB^2} + DB^2 - 2 AB \times DB$ (Th. V. C. 1).

Hence, $\overline{AC^2} = \overline{DC^2} + \overline{AB^2} + \overline{DB^2} - 2AB \times DB$.

But, $\overline{DC^2} + \overline{DB^2} = \overline{BC^2}$, in BDC.

Hence, $\overline{AC^2} = \overline{AB^2} + \overline{BC^2} - 2\overline{AB} \times DB$.

The same may also be shown if the perpendicular meets the base produced, as in the second figure. Therefore, etc.

Note.—This 8th Proposition can be very prettily drawn from the 7th, by transposing the terms of the 7th, and reducing. Let the pupil try it.

THEOREM IX.

In any triangle, a straight line drawn parallel to the base divides the other sides proportionally.

Let ABC be a triangle, and DE a line parallel to the base; then will

CD : DA :: CE : EB.

For, draw AE and DB; then, since the two triangles ADE and DEC have their bases in the same line and their vertices at the same point E, they have the same altitude; hence, they are to each other as their bases (Th. III. C. 2), or,

For a similar reason, the triangles *BED* and *DEC* are to each other as their bases; hence, we have,

BED: DEC:: BE: EC.

But the triangles AED and BED have the same base DE and the same altitude, since their vertices are in the line AB parallel to DE; hence, they are equal (Tb. III.), and

the two proportions have a couplet in each equal; hence, the remaining terms are proportional (B. II. Th. VIII.), and we have,

AD:DC::BE:EC.

Therefore, etc.

Cor. 1. By composition, we have,

AD + DC : AD : : BE + EC : BE,

or, AC:AD::BC:BE; and, in the same way, AC:DC::BC:EC.

Cor. 2. Conversely, If a line divides two sides of a triangle proportionally, it will be parallel to the third side.

Let DE divide CA and CB proportionally; then, if DE is not parallel to AB, draw DE' parallel to AB. Now CA:CD::CB:CE' (Cor. 1), but CA:CD::CB:CE byhypothesis;

hence, CE' = CE, which is absurd. Therefore, etc.

Cor. 3. Since DEC: AEC:: DC: AC and AEC: ABC::

EC:BC, and also, DC:AC::EC:BC; therefore,

DEC: AEC: AEC: ABC.

That is, the triangle AEC is a mean proportional between DEC and ABC.

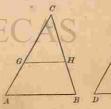

SIMILAR TRIANGLES.

THEOREM N

Triangles which are mutually equiangular are similar.

Let ABC and DEF be two triangles having the angle A = D, the angle B = E, and C = F; then will they be similar.

For, on AC take CG equal to FD, and on BC take CH equal to

FE, and draw GH; then the triangle CGH will be equal to FDE (B. I. Th. VI.) and the angle CGH will equal FDE; hence, the angle CGH equals CAB, and GH is parallel to AB (B. I. Th. IV.). Hence, we have (Th. IX. C. 1).

AC: BC:: GC: HC, or, AC: BC:: DF: EF;

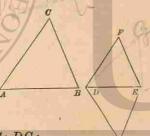

and the same may be shown for the sides containing the other equal angles; hence, the triangles are similar (D. 6). Therefore, etc.

THEOREM XI.

Triangles which have their corresponding sides proportional are similar.

Let ABC and DEF be two triangles having their corresponding sides proportional; then will they be similar.

For, if they are not similar, suppose some other triangle, as DEG, to be constructed upon the side DE, similar to ABC. Then, by the preceding theorem, we have,

AB:DE::AC:DG;

but, by hypothesis,

AB : DE :: AC : DF; hence,

we have,

DG = DF.

In the same way, it may be shown that

EG = EF.

Hence, the triangles *DEG* and *DEF* must be equal in all their parts (B. I. Th. IX.), and, therefore, mutually equi angular; hence *ABC* and *DEF* are mutually equiangular, and, consequently, similar. Therefore, etc.

THEOREM XII.

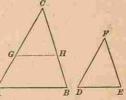

Triangles which have an angle in each equal, and the sides including them proportional, are similar.

Let ABC and DEF be two triangles having the angle C equal to the angle F, and

AC:BC::DF:EF;

then will the triangles be similar.

For, apply the angle *DFE* to *ACB*, and the triangle *DFE* will take the position *GCH*, and, from the proportion above, we shall have 2

AC:BC::GC:HC;

hence, GH is parallel to AB (Th. IX. C. 2), and the triangles GCH and ACB mutually equiangular, and therefore similar. But, GCH is equal to DFE; therefore, ACB and DFE are mutually equiangular, and similar.

THEOREM XIII.

Triangles which have their sides parallel, each to each, or perpendicular, each to each, are similar.

First. Let ABC and DEF be two triangles having the side AB parallel to DE, AC parallel C

to DF, and CB parallel to FE; then will they be similar.

For, since AC is parallel to DF and AB to DE, the angle A is equal to D (B. I. Th. V.); for a similar

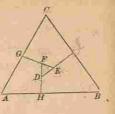

reason C is equal to F and B to E; hence, the triangles are mutually equiangular, and, consequently, similar.

Second. Let ABC and DEF be two triangles having their sides respectively perpendicular; then will they be similar.

For, produce the sides of DEF till they meet the sides of

ABC. In the trapezium GEIC, the sum of the four angles equals four right angles (B. I. Th. XIX. C. 2), and since two of the angles are right angles, the sum of the angles C and GEI equals two right angles. But the sum of GEI and FED (equals two right angles (B. I. Th. I.);

hence, the angle FED equals the angle C. In the same way it may be shown that FDE equals B, and DFE equals A; hence, the two triangles are mutually equiangular, and, consequently, similar. Therefore, etc.

THEOREM XIV.

If, in a right-angled triangle, a line be drawn from the vertex of the right angle perpendicular to the hypothenuse;

1. The two triangles thus formed will be similar to the given

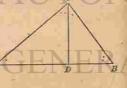

triangle and to each other.

2 Each side about the right angle will be a mean proportional between the hypothenuse and adjacent segment.

3. The perpendicular will be a mean proportional between the two segments of the hypothenuse.

Let ABC be a right-angled triangle, C the right angle, and CD the perpendicular; then,

First. The triangles ACD and ABC have each a right angle, and the angle A common; hence, the remaining angles are equal, and the triangles are similar (Th. X.).

In the same manner, we show BCD and ABC equiangular and similar; and then ADC and BDC, being both similar to ABC, are similar to each other.

Second. The two triangles being similar to the given one, we have,

AB:AC::AC:AD,

and also,

AB:BC::BC:BD.

Therefore, etc.

Third. The two triangles being similar, we have,

AD:DC::DC:DB.

Therefore, etc.

RELATION OF POLYGONS.

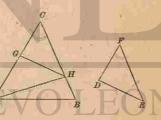

THEOREM XV.

Triangles which have an angle in each equal, are to each other as the products of the sides including those equal angles.

Let ABC and DEF be two triangles having the angle F equal to the angle C_i , then will

 $ABC: DEF::AC \times BC: DF \times EF$.

For, place the angle F on its equal C, and the triangle DEF will take the place GCH; then draw AH. Now, since the triangles AHC and GHC have their bases AC and GC in the same line AC, and vertices at

H, they have the same altitude, and are to each other as their bases; hence,

AHC: GHC:: AC: GC.

Also, since AHC and ABC have their bases HC and BC in the same line, and vertices at the point A, they have the same altitude and are as their bases; hence,

ABC:AHC::BC:HC;

BOOK III.

69

multiplying the corresponding terms of these two proportions together, and omitting the common factor AHC, we have,

 $ABC:GHC::AC\times BC:GC\times HC$, $ABC:DEF::AC\times BC:DF\times FE.$

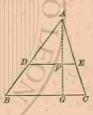

Therefore, etc.

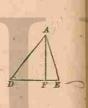

THEOREM XVI.

Similar triangles are to each other as the squares of their homologous sides.

Let ABC and ADE be two similar triangles; then will

they be to each other as the squares of any two homologous sides. Draw the altitudes AG and AF; then, since the triangles are as the product of their bases and altitudes (Th. III. C. 1),

we have,

 $ABC:ADE::BC\times AG:DE\times AF.$

But, by similar triangles, we have,

BC:DE::AB:AD,

AG:AF::AB:AD;

and, $BC \times AG : DE \times AF :: \overline{AB^2} : \overline{AD^2}$. hence,

Comparing this with the first proportion, we have,

 $ABC: ADE:: \overline{AB^2}: \overline{AD^2}.$

THEOREM XVII.

Similar polygons may be divided into the same number of triangles, similar each to each, and similarly situated.

Let ABCDE and FGHIK be two similar polygons, having the angle A equal to the angle F, B to G, C to H, etc.; then can they be divided into the same number of similar triangles similarly situated.

From the homologous angles A and F draw the diagonals AC, AD, and FH, FI. Since the polygons are similar, the triangles ABC and FGH

have the angles B and G equal, and the sides about these angles proportional; they are, therefore, similar (Th. XII.).

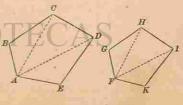

Since the triangles \overrightarrow{ABC} and \overrightarrow{FGH} are similar, the angle ACB equals FHG, and the sides AC and FH are proportional to BC and GH, and hence to CD and HI. If we take the equal angles ACB and FHG from the equal angles BCD and GHI, we have ACD equal to FHI; hence, the triangles ACD and FHI have an angle in each equal, and the sides including these angles proportional; they are, therefore, similar (Th. XII.). In a similar manner, it may be shown that ADE and FIK are similar. Therefore, etc.

THEOREM XVIII.

The perimeters of similar polygons are to each other as any two homologous sides; and the polygons are to each other as the squares of those sides.

Let ABCDE and FGHIK be two similar polygons; then

will their perimeters be to each other as any two homologous sides, B and their areas be as the squares of those sides.

First. Since the polygons are similar, we have,

AB: FG:: BC: GH:: CD: HI, etc.;

hence (B. II. Th. XII.),

AB+BC+CD+ etc.: FG+GH+HI+ etc.:: AB:FG; or, the perimeter of the first to the perimeter of the second as any side of the first to the homologous side of the second.

Second. Since the triangles are respectively similar, we

have,

 $ABC: FGH: :AC^2: FH^2;$

and also,

 $ACD: FHI:: \overline{AC^2}: \overline{FH^2};$

hence, we have, ABC: FGH:: ACD: FHI.

In a similar manner, we find,

ACD: FHI:: ADE: FIK.

Hence (B. II. Th. XII.), the sum of the antecedents, ABC + ACD + ADE, is to the sum of the consequents, FGH + FHI + FIK, as any antecedent ABC is to its consequent FGH; and, since ABC is to FGH as $\overline{AB^2}$ to $\overline{FG^2}$, we have, $ABCDE : FGHIK :: \overline{AB^2} : \overline{FG^2}$.

Therefore, etc.

Cor. The perimeters are to each other as any two homologous lines, and the polygons are as the squares of those lines.

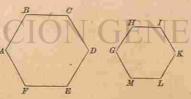

THEOREM XIX.

Regular polygons of the same number of sides are similar figures.

Let ABCDEF and GHIKLM be two regular polygons of the same number of B C sides; then will they be

similar.

For, the corresponding angles in each are equal (B. I. Th. XIX. C.

5), and the corresponding sides are proportional, since they

are equal; hence, the polygons are similar (D. 6). Therefore, etc.

Cor. Since regular polygons of the same number of sides are similar figures, their perimeters are proportional to any homologous lines, and their areas are as the squares of those lines.

PRACTICAL EXAMPLES.

1. Required the perimeter and area of a square whose sides are each 20 inches.

2. Required the perimeter and area of a rectangle whose sides are respectively 18 and 24 inches.

3. What is the area of a parallelogram whose base is 16 inches and altitude 12 inches?

4. A man has a board in the form of a triangle; what is its area if the base is 9 feet and the altitude 18 inches?

5. A farmer has a field in the form of a trapezoid; the two parallel sides are 40 and 60 rods, and the distance between them 32 rods; required its area.

*6. Required the hypothenuse of a right-angle triangle, the two sides being 3 and 4 inches respectively.

7. The sides of a triangle are 18 and 21, and the base 24; what are the sides of a similar triangle whose base is 8?

8. A man had a lot in the form of a right-angle triangle; the hypothenuse is 78 and one side 30; required the other side and the area.

9. A ladder 65 feet long is placed against a house, so that its foot is 25 feet from the house; how high does it reach?

- 10. A pole was broken 75 feet from the top, and fell so that the end struck 60 feet from the foot; required the length of the pole.

11. A has a triangular piece of ground, the base of the triangle being

The numbers 3, 4, and 5 are the smallest integers which can express the relation of the three sides of a right-angle triangle. It is a Bent that we may have an infinite number of right-angle triangles with their a des in this ratio. Thus, 6, 8, 10; 9-12, 15, etc. Another integral relation of sides is 5, 12, 13.

20 rods; what is the base of a similarly-shaped lot containing 4 times as much land?

Ans. 40 rods.

12. A man has a lot 40 rods long and 23 rods wide; what are the dimensions of a similar lot 9 times as large?

Ans. 120: 69.

13. A ladder, whose length is 91 feet, stands close against a building, how far must it be drawn out at the bottom that the top may be lowered 7 feet?

14. A ladder 130 feet long, with its foot in the street, will reach on one side to a window 78 feet high, and on the other to a window 50 feet high; what is the width of the street?

Ans. 224 feet.

15. There is a rectangular field whose sides are 25 yards and 16 yards respectively; what is the side of a square field of equal area?

Ans. 20 yards.

16. If it cost \$328 to put a fence around a farm 50 rods long and 32 rods wide, how much less will it cost to enclose a square farm of equal area with the same kind of fence?

Ans. \$8.

17. The gable ends of a house are each 48 feet wide, and the perpendicular height of the ridge above the eaves is 10 feet; how many feet of boards will it take to board up both gables?

Ans. 480.

18. A man has a field in the form of a rectangle which contains 40 acres; what are its dimensions if the length is twice the breadth?

Ans. Length, 113.136 rods; width, 56.568 rods.

19. A cemetery containing 60 acres is laid out in such a manner that its length is equal to three times its width; required the dimensions of the cemetery.

Ans. Length, 169.704 rods; width, 56.568 rods,

20. A general wishing to draw up his corps in the form of a square, found by the first trial he had 100 men over; he then increased the side of the square by 2 men, and found he lacked 136 men to complete the square; how many men had he in the corps?

Ans. 3464.

21. A man has a square yard containing $\frac{1}{10}$ of an acre; he makes a gravel walk around it which occupies $\frac{15}{62}$ of the whole yard; what is the width of the walk?

Ans. 4 feet 11 inches

22. In a triangle the two sides are 13 and 15, respectively, and the perpendicular from the vertex of the angle which they form to the opposite side, 12; required the third side.

Ans. 14.

EXERCISES FOR ORIGINAL THOUGHT.

- 1. Two squares are to each other as the squares of their diagonals.
- 2. Two similar parallelograms are to each other as the squares of their diagonals
- 3. Prove that the diagonals of a rectangle are equal to each other.
- 4. Prove that the greater diagonal of a parallelogram is opposite the greater angle.
- 5. Show where a line from the vertex of a triangle must be drawn to divide the triangle into two equal parts.
- 6. Prove that the ratio of the side of a square to its diagonal is as 1 to the square root of 2.
- 7. The straight line joining the middle points of the oblique sides of a trapezoid will be parallel to the other sides, and equal to half their
- 8. The four lines joining the middle points of the adjacent sides of a quadrilateral form a parallel gram.
- 9. The lines drawn from the vertices of the three angles of an equilateral triangle, perpendicular to the opposite sides of the triangle, will intersect each other in the same point.
- 10. The line which bisects the vertical angle of a triangle divides the base into two parts which are proportional to the adjacent sides.
- 11. If a line be drawn parallel to the base of a triangle, and lines be drawn from the vertex of the triangle to the base, these lines will divide the base and parallel proportionally.
- 12. Triangles which have an angle in each equal, are to each other as the rectangles of the sides including those angles.

BOOK IV.

OF THE CIRCLE.

DEFINITIONS.

1. A CIRCLE is a plane bounded by a curve line, every point of which is equally distant from a point within called the centre.

2. The CIRCUMFERENCE is the bounding line of a circle. An Arc is any part of the circumference; as, BD.

- 4. The DIAMETER is a straight line passing through the centre and terminating at both extremities in the circumference; as, AB.
- 5. A CHORD is a straight line joining the extremities of an are; thus, BD is a chord.
- 6. A SEGMENT is a portion of the circle included between an arc and its chord; as, *DBE*.
- 7. A SECTOR is a portion of the circle included by an arc and the radii drawn to its extremities; as, *DCBE*.
- 8. A TANGENT is a straight line which touches the circumference in one point; thus, AB is a tangent. The point E is called the point of tangency.

9. A SECANT is a straight line which cuts the circumference in two points; thus, CD is a secant.

10. An INSCRIBED ANGLE is an angle whose vertex is in the circumference and whose sides are chords; as, ABC in the next figure.

11. An Inscribed Polygon is a polygon whose sides are chords, the vertices of the angles being in the circumference; as, ABCDEF.

12. A POLYGON is circumscribed about a circle when all of its sides are tangents to the circumference. The circle is at the same time inscribed in a polygon.

AXIOMS.

- 1. The radii, and also the diameters, of a circle, or of equal circles, are equal.
- 2. Every diameter is double the radius, or is equal to the sum of two radii.
- 3. A straight line can cut a circumference in only two points.

Analysis.—This book treats of the nature of the circle, the measurement of angles, the finding of the circumference, the measurement of the area of a circle, and the relation of the circumferences, and also if the areas of circles. The method of treatment in finding the circumference and area, and also their relations, is to regard the circle is a polygon of an infinite number of sides, and derive the principles from those of polygons. By a simplification of the subject, we embrace in one book what is usually given in two.

NATURE OF THE CIRCLE.

THEOREM I.

The diameter of a circle is greater than any other chord.

Let AB be any chord; then will it be less than any diameter.

For, from the point A draw the diameter AD, and draw also the radius CB. Then, in the triangle ACB, the sum of the sides AC and CB is greater than AB (B. I. A. 10. C.). But AC+

CB equals AD (Ax. 2); hence, AD is greater than AB.

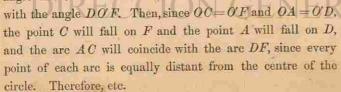

Therefore, etc.

THEOREM II.

In the same circle or equal circles, equal angles at the centre intercept equal arcs on the circumference.

In the equal circles ABC and DEF let the angle AOC equal DOF; then will the arc AC be equal to the arc DF.

For, apply the circle ABC to the circle DEF so that the angle ACC shall coincide

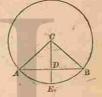

Cor. Conversely.—In the same circle or equal circles, equal arcs subtend equal angles at the centre. For, if we apply the equal arcs AC and DF, placing the point C on F, they will coincide, and the point A will fall on D; hence, the line OC will coincide with OF and OA with OD, and the angle AOC will be equal to DOF.

THEOREM III.

Any radius which is perpendicular to a chord bisects the chord and also the arc subtended by the chord.

Let AB be the chord, and CD the radius perpendicular to it; then will AD = DB and AE = EB.

First. Draw the radii CA and CB; then the angle ACD equals DCB (B. I. Th. X. C. 1), and the triangles ACD and DCB are equal (B. I. Th. VI.); hence, the side AD equals DB.

Second. Since the triangles ACD and DCB are equal, the angle ACE equals ECB; hence, the are AE equals the are EB (Th. II. C.).

THEOREM IV.

Through three points not in the same straight line a circumference may be made to pass.

Let A, B, and C be any three points not in the same straight line; then may a circumference be described through them.

Draw AB and BC, and at E and D, the middle points of AB and BC, draw perpendiculars, and unite the points E and D. Now, since OED + ODE is less than two right angles, the perpendiculars will meet

in some point, as O (B. I. Th. IV. C. 3). Draw OA, OB, and OC; then OA = OB (B. I. Th. XIV.), and, for the same reason, OB = OC; hence, a circumference described from O as a centre will pass through the three points A, B, and C.

Cor. It may also be readily shown that but one circumference can be made to pass through three points.

THEOREM V.

If a straight line is perpendicular to a radius at its extremity, it will be tangent to the circle at that point.

Let the straight line AB be perpendicular to the radius CD at D; then will it be tangent to the circle at the point D.

For, take any point of AB, as E, and draw the line CE. Now, CE is greater than CD (B. I. Th. XIV.); consequently, the point E will be without the circle, and hence the line AB touches

the circumference in only one point: it is therefore tangent to it at the point D (D. 8). Therefore, etc.

Cor. Conversely.—A tangent to the circle is perpendicular to the radius drawn to the point of contact.

For any line, as CE, is greater than CF, or its equal CD; hence, CD, being the shortest line from C to the tangent, is perpendicular to the tangent at D (B. I. Th. XIV.). Therefore, etc.

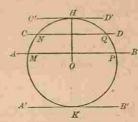

THEOREM VI.

Two parallel lines intercept equal arcs on the circumference.

There may be three cases: first, when both lines are secants; second, when one is a secant and the other a tangent; third, when both are tangents.

First. Let AB and CD be two lines cutting the circle; then will the arcs MN and PQ be equal.

For, draw the radius OH perpendicular to the chord NQ; it will be perpendicular to MP (B. I. Th. III. C.), and will bisect the arcs NHQ and MHP at the point H (Th. III.); hence, NH equals HQ and MH equals HQ; and, therefore,

79

MH-NH=PH-QH, or MN equals PQ. Therefore, etc.

Second. If one of the lines, as C'D', is a tangent. Then the radius OH, drawn to the point of contact, H, is perpendicular to the tangent C'D' (Th. V.), and consequently to its parallel AB. Since OH is perpendicular to the chord MP, it bisects its arc MHP (Th. III.); hence, arc MH equals arc PH.

Third. If both lines, as C'D' and A'B', are tangents. Draw any secant, as AB, parallel to A'B'; it will be parallel to C'D' (B. I. Th. IV. C. 2). By the second case we have arc MK = arc PK, and arc MH = arc PH; adding, we have MH + MK = PH + PK, or arc HMK = arc HPK.

Cor. 1. In the case of parallel tangents it is evident that each arc is a semi-circumference.

Cor. 2. The straight line joining the points of contact of two parallel tangents is a diameter.

Scholium. Regarding a tangent as a secant whose two points of intersection coincide, the demonstration of the first case of the theorem may be regarded as including the other two cases.

MEASUREMENT OF ANGLES.

THEOREM VII.

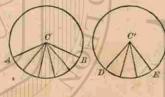

In the same circle or in equal circles, two angles at the centre have the same ratio as their intercepted arcs.

Let ACB and DC'E be two angles at the centre of equal

circles, and AB and DE their intercepted arcs; then will

ACB : DC'E : : AB : DE.

First. Suppose some common unit is contained 5 times in the arc AB and 3 times in the arc DE; then

arc AB : arc DE : : 5 : 3.

Draw radii to the several points of division of the arcs; the angles thus formed will be equal, since their arcs are equal (Th. II. C.); hence the angle ACB will consist of 5 equal parts and the angle DC'E of 3 such equal parts; therefore

angle ACB: angle DCE::5:3.

Comparing the two proportions, we have

angle ACB: angle DC'E:: are AB: are DE.

Second. Now this is true whatever the size of the unit of measure; hence it is true when the unit of measure becomes indefinitely or infinitely small, as it must when the two arcs are incommensurable. Therefore, any two angles at the centre of the same or equal circles are to each other as their intercepted, arcs.

THEOREM VIII.

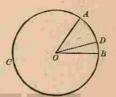

An angle having its vertex at the centre of a circle is measured by the arc intercepted between its sides.

Let AOB be an angle at the centre of the circle ACB, and AB its intercepted arc; then will AB be the measure of the angle AOB.

For, let BOD be the unit of measure of the angle AOB, and the arc BD be the unit of measure of the arc BA; then, by Theorem VII., we have

 $\frac{AOB}{DOB} = \frac{AB}{DB}.$

Now, AOB divided by DOB equals the number of units in the angle AOB, and AB divided by DB equals the number of units in the arc AB; hence the number of units in the angle is equal to the number of units in the arc; therefore the arc may be used as the measure of the angle.

Scholium 1. This theorem is usually expressed thus: An angle at the centre is measured by its intercepted arc. The statement is, however, rather conventional, "measured by" meaning "having the same numerical measure." Both angle and are have the same numerical measure; hence the arc may be assumed as the measure of the angle.

Scholium 2. It would seem more natural to measure an angle by a quantity of the same kind, and for this purpose the right angle would naturally be taken as the unit of measure. It has been found more convenient, however, to use the arc of a circle as the measure of an angle, and for this purpose the circumference has been divided into degrees, minutes, and seconds, as before explained.

THEOREM IX.

An angle having its vertex at the circumference of a circle is measured by half the arc intercepted between its sides.

There may be three cases; first, when the centre of the circle is on one of the sides of the angle; second, when it is without the angle.

First. Let ABC be the angle, having its vertex at B, and O be the centre of the circle; then will ABC be measured by one-half of AC.

For, draw the radius AO; then the exterior angle AOC is equal to the sum of the opposite interior angles ABO and

OAB (B. I. Th. XIII. C. 5). But, the triangle AOB being isosceles, the angles A and B are equal; and, consequently, the angle AOC is double the angle ABC. But AOC, being at the centre, is measured by the arc AC (Th. VIII.); hence, the angle ABC is measured by one-half of the arc AC.

Second. Let ABC be the angle, and O the centre of the circle; then will ABC be measured by one-half of ADC.

For, draw the diameter BD; then, from what we have just shown, the angle ABD is measured by one-half of AD, and the angle DBC by one-half of DC; hence, their sum, or the angle ABC,

is measured by one-half of the sum of AD and DC, or one-half of ADC.

Third. Let ABC be the angle, and O the centre being without the angle; then will ABC be measured by one-half of AC.

For, draw the diameter BD; then, ABD is measured by

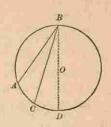

one-half of AD, and CBD is measured by one-half of CD; hence, ABC, their difference, is measured by one-half of AD minus CD, or one-half of AC. Therefore, etc.

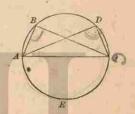

Cor. 1. All the angles ABC, ADC, inscribed in a semicircle are right angles, being measured by one-half of the semi-circumference AEC (Th. IX.).

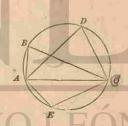

Cor. 2. All the angles ABC, ADC, etc., inscribed in a segment greater than a semicircle are less than right angles, being measured by less than one-half of a semi-circumference. Any angle AEC inscribed in less than a semicircle is greater than a right angle, being measured by more than one-half of a semi-circumference.

Cor. 3. All the angles inscribed in the same segment are equal, being measured by one-half of the same arc.

Scholium. A right angle is measured by one-half a semicircumference, or a quadrant.

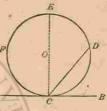

THEOREM X.

The angle formed by a tangent and a chord is measured by half the arc intercepted between its sides.

Let AB be a tangent to the circle at C, and CD a chord meeting the tangent at C; then will the angle ACD be measured by one-half the arc CED.

For, draw the diameter CE. The angle ACE is a right angle, and is measured by half the semi-circumference CFE (Th. IX. S.); the angle ECD is measured by half the arc ED (Th. IX.); hence, the angle ACD, which equals ACE + ECD, is measured by half the sum of the arcs CFE and ED, or by half the arc CFD. 4 Therefore, etc.

THEOREM XI.

An angle formed by two chords which intersect is measured by half the sum of the intercepted arcs.

Let AEC be an angle formed by the intersection of the chords AB and CD; then will it be measured by half the sum of AC and DB.

For, draw DF parallel to AB; then the arc AF equals the arc DB (Th. VI.), and the angle FDC equals the angle AEC (B. I. Th. III.). Now, the angle FDC is measured by onehalf the arc FC (Th. VII.); hence, the angle AEC is measured by one-half of FC, or $\frac{1}{2}(AC+AF)$, or $\frac{1}{2}(AC+DB)$ Therefore, etc.

THEOREM XII.

The angle formed by two secants is measured by half the difference of the intercepted arcs.

Let the angle ABC be formed by the two secants ABand CB; then will it be measured by one-half the difference of the arcs AC and ED.

For, draw DF parallel to AB; then the arc AF is equal to the arc ED, and the angle FDC equal to ABC. Now, the angle FDC is measured by one-half of the arc FC; hence, ABC is measured by one-half of FC; that is, by

THEOREM XIII.

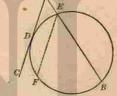

The angle formed by a secant and a tangent is measured by half the difference of the intercepted ares.

Let AB be a secant cutting the circle in E, and AC a tangent at the point D; then will the

angle BAC be measured by one-half of the difference of the arcs DB and DE.

For, draw EF parallel to AC; then the angle FEB equals CAB, and the arc DE equals arc DF. Now, the angle FEB is measured by one-half of FB;

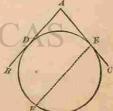

THEOREM XIV.

The angle formed by two tangents is measured by half the difference of the intercepted arcs.

Let AB be a tangent at D, and AC a tangent at E; then will the angle BAC be measured by half the difference of the arcs DFE and DE.

For, draw EF parallel to AB; then the angle FEC equals BAC, and the arc DE equals the arc DF. Now, the angle FEC is measured by half the

arc FE (Th. X.); hence BAC is measured by half the arc FE; but arc FE = DFE - DF, or DFE - DE; hence BAC is measured by $\frac{1}{2}(DFE - DE)$. Therefore, etc.

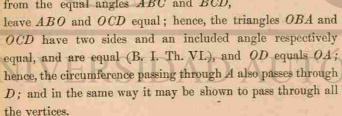

THE CIRCUMFERENCE AND AREA.

THEOREM XV.

The circumference of a circle may be circumscribed about a regular polygon, and it may also be inscribed within it.

Let ABCD be a regular polygon; then can the circumference of a circle be circumscribed about it.

Through the three vertices A, B, and C, describe a circumference; its centre O will be in OK drawn perpendicular to BC at its middle point K. The triangle BOC being isoceles, the angles OBC and OCB are equal, which, being subtracted from the equal angles ABC and BCD,

Second. Since the triangles AOB, BOC, etc. are all equal, their altitudes are equal; hence, a circumference described from O as a centre with the radius OK will touch all the chords at their middle points, and, consequently, be inscribed within the polygon. Therefore, etc.

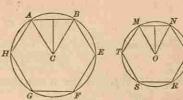

THEOREM XVI.

The circumferences of circles are as their radii, and their areas are as the squares of their radii.

Let C and O be the centres of two circles whose radii are CA and OM; then

will their circumferences be to each other as their radii, and their areas as the squares of their radii.

Inscribe in the circles regular polygons of the same number of sides. These polygons being similar figures, their perimeters are to each other as any two homologous lines CA and OM, and their areas are as the squares of those lines (B. III. Th. XVIII. C.); and this is true whatever the number of sides; hence, it is true if the number of sides is infinite, and the polygon becomes the circle. Hence, we have,

circ. CA: circ. OM:: CA: OM; and, also, area CA: area OM:: $\overline{CA^2}$: $\overline{OM^2}$.

Cor. 1. Since the radii of circles are to each other as the diameters, we have the circumferences to each other as the diameters, and the areas as the squares of the diameters.

Cor. 2. From this we see that the circumference of a circle is to its diameter as the circumference of another circle to its diameter; hence, the ratio of the circumference to the diameter is a constant quantity. This constant ratio mathematicians represent by π , the Greek letter

BOOK IV.

89

p, called pi. Letting C represent the circumference and D the diameter we have $\pi = \frac{C}{D}$.

Note.—This symbol # is of great importance in mathematics: the pupil should be very careful to thoroughly understand its signification and use.

THEOREM XVII.

The circumference of a circle equals the diameter multiplied by π .

Since the ratio of the circumference to the diameter is represented by π , we have,

$$\frac{C}{D} = \pi$$
; and, multiplying by D ,

we have,

$$C = \pi. D.$$

Therefore, etc.

Cor. Since the diameter is twice the radius, if we substitute 2 R for D, we will have,

$$C = \pi \times 2 R$$
, or $C = 2 \pi R$.

Hence, the circumference equals the radius multiplied by 2π .

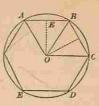

Remark.—The value of π cannot be exactly expressed in numbers. The number generally used is 3.1416, which is sufficiently accurate for practical purposes.

THEOREM XVIII.

The area of a circle is equal to the circumference multiplied by one-half the radius.

Let O be the centre of a circle whose radius is OA, and circumference ABCD, etc.; then will its area be equal to circ. $OA \times \frac{1}{2} OA$.

Inscribe in the circle a regular polygon ABCD, etc., and draw the radii OA, OB, etc., and the perpendicular OE. The area of each triangle of the polygon is equal to its base multiplied by one-half its altitude, and since the alti-

tudes are equal being radii of the inscribed circle, the area of the polygon is equal to the sum of the bases, or its perimeter multiplied by one-half of OE. Now, this is true whatever the number of sides; hence, it is true when the number of sides is infinite and the polygon becomes a circle. In this case the perimeter becomes the circumference, and the line OE, the radius. Therefore, the area of a circle is equal to the circumference multiplied by one-half of the radius.

Cor. The area of a circle is equal to the circumference multiplied by one-fourth of the diameter.

THEOREM XIX.

The area of a circle equals the square of the radius multiplied by π .

Let C be the centre of a circle; denote its radius CA by R, and its area by $area\ CA$; then from the previous theorem we have,

area CA = circ. $CA \times \frac{1}{2}R$;

but, circ. $CA = 2 \pi R$ (Th. XVII. C.);

hence, area $CA = 2 \pi R \times \frac{1}{2} R$,

which, reduced, gives,

area $CA = \pi R^2$.

Therefore, etc.

Cor. In a similar manner, we find that area $CA = \pi \ ^1_4D^2$, or area $CA = \frac{1}{4} \pi \ D^2$.

Scholium. The finding the exact length of the circumference of a circle is called the rectification of the circle. The finding of the area of a circle is called the quadrature of or squaring the circle. Both of these are celebrated problems, and can only be solved approximately, as may be shown by Calculus.

It was stated in Theorem XVII. that the value of π is about 3.1416. This value is generally determined by finding a numerical expression for the area of a circle whose radius is unity, which area may be shown equal to the ratio of the circumference to the diameter. The solution is given in the following proposition.

THEOREM XX.

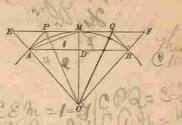

Problem.—To find the numerical value of π , the ratio of the circumference to the diameter.

The area of a circle equals πR^2 ; but when R=1, the area of the circle equals π ; hence, we may find the value of π by finding the area of a circle whose radius is 1. As a circle is a polygon of an infinite number of sides, by constructing successive similar inscribed and circumscribed polygons of double the number of sides, two may be found whose areas so nearly approach each other that either of them may be taken for the area of the circle.

Let C be the centre of the circle, AB the side of an inscribed, and EF of a circumscribed, polygon. Draw the chord AM, and the tangents AP and BQ; then AM will be the side of an inscribed, and PQ of a circumscribed poly-

gon of double the number of sides. Draw CE, CP, CM and CF.

Let P represent the area of the given circumscribed polygon; p, the area of the given inscribed polygon; P', the area of a circumscribed polygon of dou-

ble the number of sides; and p', the area of an inscribed polygon of double the number of sides. Also, represent the triangles CEM, CAD, CPQ and CAM, which are respectively like parts of P, p, P' and p', by T, t, T' and t'.

1. The triangle CAM is a mean proportional between CAD and CEM (B. III. Th. IX, C. 3), hence,

whence,

$$+ P: p':: p': p$$
 (B. II. Th. X.);

therefore,

$$p' = \sqrt{p \times P}$$
 are $a(1)$ must be dygout less

2. Because of a common altitude, CAM and CAD are to each other as CM to CD, and CEM to CPM as EM to PM;

hence,

and,

$$T: \frac{1}{2}T'::EM:PM,$$

by division, $T - \frac{1}{2}T' : \frac{1}{2}T' : : EP : PM$, since EM - PM = EP.

The triangles CAD and AEP are similar; hence,

AC: CD: EP: AP, or, since AC = CM and AP = PM,

CM:CD::EP:PM.

Hence, from the first and third proportions, we have,

ence,
$$p':p::2P-P':P'$$
, (B. II, Th. X.)

$$p' + p : p :: 2P : P';$$

$$P' = \frac{2p \times R}{p' + p}$$

BOOK IV.

9:

Now if p and P are squares, the radius being 1, the area of P is 4; and the side of p is $\sqrt{2}$ (B. III. Th. VI. C. 3); hence the area of p is 2;

then, from (1), $p' = \sqrt{8} = 2.8284271$,

and, from (2), $P = \frac{16}{2 + 1/8} = 3.3137085$;

which are the areas of the inscribed and circumscribed octagons; and in the same manner we may find the areas of polygons of 16,32, etc. sides. For 8192 sides, the area of the inscribed polygon is 3.1415923 +, and of the circumscribed polygon, 3.1415928 +, either of which may be taken for the area of the circle whose radius is 1; and, since we have shown this to be the value of π , we have $\pi = 3.14159 +$. Scholium. The value of π is generally taken to be 3.1416.

Note.—We invite special attention to the method of treating the circumference and area of the circle, and also to the simple and concise method of presenting the derivation of the value of π , as given in the last proposition-

PRACTICAL EXERCISES.

- 1. The radius of a circle is 6 inches; what is its circumference?
- 2. The diameter of a circle is 8 inches; what is its area?
- 3. The circumference of a circle is 50.2656 feet; required the radius,

Ans. 8 1

4. The area of a circle is 490.875 square inches; required the diameter and circumference.

Ans. Diameter, 25; circumference, 78.54.

- 5. The distance around a circular park is 180 rods; required the area of the park.

 Ans. 16 A. 18.23 P.
- 6. What is the length of an arc of 75° on the circumference of a circle whose radius is 5 feet?

 Ans. 6.545 feet.
- 7. How many degrees in an arc 18 inches long, on a circumference whose radius is 5 feet?

 Ans. 17° 11′ 19′′.

8. A circle 20 feet in diameter is circumscribed by another circle 30 feet in diameter; what is the area of the space included between them?

9. A has a circular garden whose diameter is 18 rods, and B has one whose area is 27 times as great; what is the diameter of B's garden?

Ans. 30 rods.

10. Find the side of a square inscribed in a circle whose diameter is 5 feet.

Ans. 3.535 feet.

11. Within a circular park 160 rods in circumference is a circular lake 80 rods in circumference; required the width of the ring of land surrounding the lake.

Ans. 12.782 rods.

12. Deborah has a circular garden and John a square one, and the distance around each is 120 rods; which contains the most land, and how much?

Ans. 245.95 square rods.

13. A man has a square garden and his wife a circular one, and each garden contains one acre; how much further around is one than the other?

Ans. 5.756 rods.

14. The area of a circle is 314.16; if this circle be circumscribed by a square, required the area of the part between the circumference and the perimeter of the square.

Ans. 85.84.

15. The area of a circle is 4 acres; required the side of the inscribed square, and the area of the part of the circle between the circumference and perimeter of the square.

Ans. 1 A. 1 R. 32 P.

THEOREMS FOR ORIGINAL THOUGHT.

- 1. If two circumferences intersect, the distance between their centres will be less than the sum of their radii and greater than the difference.
- If two circumferences intersect, the points of intersection will lie in a perpendicular to the line joining their centres, and at equal distances from it.
- 3. In equal circles the greater arc has the greater chord, and, conversely, the greater chord subtends the greater arc.
- 4. In equal circles, equal chords are equally distant from the centre, and the greater chord is nearer the centre.
- 5. If we inscribe a square in a circle, the radius is to the side of the inscribed square as 1 is to $\sqrt{2}$.

- 6. If a regular hexagon be inscribed in a circle, each side will be equal to the radius of the circle.
- 7. The area of a triangle is equal to the perimeter multiplied by onehalf the radius of the inscribed circle.
- 8. In any inscribed quadrilateral, the sum of the opposite angles is equal to two right angles.
- 9. When a quadrilateral circumscribes a circle, the sums of its opposite sides are equal.
- 10. When the radius of a circle is unity, its area and semi-circumference are numerically equal.

PRACTICAL PROBLEMS IN GEOMETRI-CAL CONSTRUCTION,

INVOLVING THE PRINCIPLES OF BOOKS I., II., III., AND IV.

THE following problems are solved by the principles of the previous books. The solution of a few is given in full; in others, the construction is given, and the reason for the solution indicated by referring to the theorem or theorems upon which it depends. The pupil will give the explanation in full.

The object of these is to teach the pupil to draw accurately upon paper. They are of great use in drawing the notes of a survey, or in representing any geometrical figure upon paper. The pupils need two instruments, a rule and compasses; with these all the following problems may be readily solved

PROBLEM I.

To bisect a given straight line.

Let AB be the given straight line. From A and B, as centres, with a radius greater than one-half of AB, describe arcs intersecting at E and F; draw the line EF; then will C be the middle point of AB. For, E and F are each equally distant from A and B; hence, EC bisects AB (B. I. Th. XIV. C. 3).

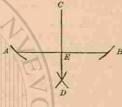

PROBLEM II.

From a given point without a straight line to draw a perpendicular to the line.

Let AB be the given line, and C the given point. From C as the centre, with a radius suffi-

ciently great, describe an arc cutting the line AB in the two points A and B; then from A and B as centres, with a radius greater than onehalf of AB, describe two arcs cutting each other in D, and draw CD;

it will be the perpendicular required (B. I. Th. XIV. C. 3).

PROBLEM III.

At a given point in a straight line to erect a perpendicular to that line.

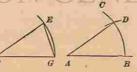

Let AB be the given line, and C the given point. Then, in the line AB take the points A and B. equally distant from C, and with A and B as centres, and a radius greater than one-half of AB, describe two arcs cutting each other at D; draw DC; it will be the perpendicular required (B. I. Th. XIV. C. 3).

PROBLEM IV.

At a point on a given straight line to make an angle equal to a given angle.

Let A be the given point, AB the given line, and EFG the given angle.

ven angle. From the point F as a centre,

with any radius FG, describe the arc EG. From A as a centre, with the same radius, describe the arc CB; then, with a radius equal to the chord EG, describe an arc from B as a centre, cutting the arc CB in D, and draw AD; then will the angle DAB equal EFG (B. I. Th. IX.).

PROBLEM V.

To bisect a given arc, or a given angle.

First. Let ADB be the given arc, and C its centre. Draw the chord AB, and from C draw CD perpendicular to AB (P. II.); then will CD bisect AB (B. IV. Th. III.).

Second. Let ACB be the given angle. Then, with C as a centre and any radius CA, describe the arc AB, and bisect this arc by the line CD, as in the previous case; then will CD bisect ACB (B. IV. Th. III.).

PROBLEM VI.

Through a given point to draw a straight line parallel to a given straight line.

Let A be the given point and CD the given line. From A as a centre, with a radius greater than the shortest distance from A to CD, describe an indefinite arc DE; from D as a centre, with the same radius, describe the arc AF; take DE equal to AF, and draw AB; AB will be the parallel required.

For, drawing AD, we have ADF = DAE (Prob. IV.); hence, AE and CD are parallel (B. I. Th. IV.).

PROBLEM VII.

Two angles of a triangle being given, to find the third.

Let M and N be the given angles. DDraw the indefinite line AB; at any point, as C, construct the angle ACD equal to M, and the angle DCE equal to N; then will ECB equal the third angle.

PROBLEM VIII.

Given two sides and the included angle of a triangle, to construct the triangle.

Draw the indefinite line AD; take AB equal to one of the given sides; at A construct the angle A equal to the given angle, and take AC equal to the other given side; draw BC; then will ABC be the required triangle (B. I. Th. VI.).

PROBLEM IX.

Given one side and two angles of a triangle, to construct the triangle.

If the angles are not adjacent, find the third angle by P. VII.; we then have two angles and the included side, and proceed thus:-

Draw the indefinite line AD; take AB equal to the given side; at A make the angle BAC equal to one of the angles; at B make the angle ABC equal

the other angle; then produce AC and BC till they meet, and ABC will be the required triangle (B. I. Th. VII.).

PROBLEM X.

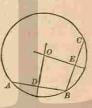

Given two adjacent sides of a parallelogram and the included angle, to construct the parallelogram.

Draw the indefinite line AE, and upon it take AB equal to one of the sides. At A construct the angle BAD equal to the given angle, and take AD equal to the other given side. Draw DC parallel to AB, and BC parallel to AD; then will ABCD be the parallelogram required (B. I. Th. XV. C. 3).

PROBLEM XI.

To find the centre of a given circumference or arc.

Take any three points, A, B, and C, on the circumference or are, and unite them by the lines AB and BC. Bisect these chords by the perpendiculars DO and EO: then will their intersection O be the centre of the circle (B. IV. Th. IV.).

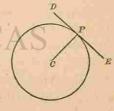

PROBLEM XII.

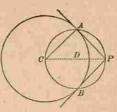

Through a given point to draw a tangent to a given circle. First. Suppose the given point P to be in the circumference.

Find C, the centre of the circle (P. XI.); draw the radius CP; and then through P draw the perpendicular DE; DE will be the tangent required (B. IV. Th. V.).

Second. Suppose the given point P

to be without the circle. Join P and the centre of the circle; bisect PC in D; with D as a centre, and a radius DC, describe the circumference intersecting the given circumference in A and B; draw PA or PB; then

each of those will be the tangent required.

For, since CAP is a semicircle, the angle CAP is a right angle (B. IV. Th. IX. C. 1); hence, AP is a tangent (B. IV. Th. V.).

PROBLEM XIII.

To divide a given line into any number of equal parts.

Let AB be the given line, and suppose we wish to divide it into any number, say 5 equal parts.

Through A draw the indefinite line AE, making any angle with AB. Take AC of any convenient length, and apply it 5 times to AE; join B with the last point of the division; and through the other points of division draw lines parallel to EB; then will AB be divided into 5 equal parts.

For, since DC and BE are parallel, we have (B. III. Th. IX.),

AC:AE::AD:AB.

But AC is one-fifth part of AE; hence, AD is one-fifth part of AB.

PROBLEM XIV.

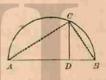

To divide a given line into parts proportional to given lines. Let AB be the given line, to be divided into parts proportional to the given lines P, Q, and R. Through A draw AG, making any angle with AB. On AG lay off AC equal P, CE equal Q, EG equal R; draw BG, and from the points C and E draw CD and EF parallel to GB; then will AD, DF, and FB be proportional to AC, CE, and EG (B. III. Th. IX.).

PROBLEM XV.

To construct a mean proportional to two given lines.

Let P and Q be the two given lines. Draw an indefinite

line, and on it lay off AD equal to P, and DB equal to Q; on AB as a diameter describe a semicircle, and draw DC perpendicular to AB; then, in the triangle ACB, will DC be a mean proportional to AD and DB (B. III. Th. XIV.).

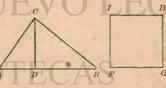

PROBLEM XVI.

To construct a square equal to a given triangle.

Let ABC be the given triangle, AB its base, and CD its altitude.

Find a mean proportional between CD and one-half of AB (Prob. XV.). Let FG be that mean proportional, and on it, as a side, construct

the square FGHI; this will be the square required. For, by the construction, we have $\overline{FG^2} = \frac{n}{2}AB \times CD$, which equals the area of ABC.

PROBLEM XVII.

To inscribe a regular hexagon in a circle.

Suppose the problem to be solved, and that ABCDEF

is a regular hexagon; draw the radii OB and OC. Now, the arc BC is one-sixth of a circumference, or 60°; hence, the angle BOC is 60°, and the other angles OBC and BCO equal 180° minus 60°, or 120°, and, OB being equal to OC, the angles OBC and BCO are equal;

hence, each is equal to one-half of 120°, or 60°. Consequently, the triangle *OBC* is equiangular, and therefore equilateral; hence, the side *BC* is equal to the radius *OB*. Therefore, to inscribe a regular hexagon in a circle, we apply the radius six times as a chord to the circumference.

PROBLEMS FOR ORIGINAL THOUGHT.

- 1. Given the three sides of a triangle, to construct the triangle.
- 2. Given two sides of a triangle, and the angle opposite one of them, to construct the triangle.
- 3. To inscribe a circle in a given triangle.
- 4. To inscribe a circle in a square, and a square in a circle.
- 5. To find the side of a square which shall be equal to the sum of two given squares.
- 6. To find the side of a square which shall be equal to the difference between two given squares.
- 7. To construct a rectangle equal in area to a given triangle
- 8. To find a fourth proportional to three given lines.
- 9. On a given line to construct a rectangle which shall be equal to a given rectangle.
- 10. To construct a square that shall be equal in area to a given parallelogram.

BOOK V.

PLANES AND THEIR ANGLES.

DEFINITIONS.

- 1. A PLANE is a surface such that a straight line connecting any two of its points will lie entirely in the surface.
- 2. A straight line is PERPENDICULAR TO A PLANE when it is perpendicular to every line of the plane passing through its foot. The *foot* is the point where the line meets the plane.

Reciprocally, the plane is also perpendicular to the line.

3. A straight line is PARALLEL TO A PLANE when it cannot meet the plane, however far both be produced.

Reciprocally, the plane is also parallel to the line.

- 4. Two Planes are Parallel when they cannot meet, however far both be produced.
- 5. When two planes meet, they form a line, which is called their LINE OF INTERSECTION.
- 6. A DIEDRAL ANGLE is the divergence of two planes.
 The line in which the planes intersect is called the edge of the angle; the planes

are called the faces of the angle.

A diedral angle is measured by the angle formed by two lines, one in each plane and perpendicular to the edge at the same

point. Thus, the diedral angle in the margin is measured by the angle ACB.

PROBLEM XVII.

To inscribe a regular hexagon in a circle.

Suppose the problem to be solved, and that ABCDEF

is a regular hexagon; draw the radii OB and OC. Now, the arc BC is one-sixth of a circumference, or 60°; hence, the angle BOC is 60°, and the other angles OBC and BCO equal 180° minus 60°, or 120°, and, OB being equal to OC, the angles OBC and BCO are equal;

hence, each is equal to one-half of 120°, or 60°. Consequently, the triangle *OBC* is equiangular, and therefore equilateral; hence, the side *BC* is equal to the radius *OB*. Therefore, to inscribe a regular hexagon in a circle, we apply the radius six times as a chord to the circumference.

PROBLEMS FOR ORIGINAL THOUGHT.

- 1. Given the three sides of a triangle, to construct the triangle.
- 2. Given two sides of a triangle, and the angle opposite one of them, to construct the triangle.
- 3. To inscribe a circle in a given triangle.
- 4. To inscribe a circle in a square, and a square in a circle.
- 5. To find the side of a square which shall be equal to the sum of two given squares.
- 6. To find the side of a square which shall be equal to the difference between two given squares.
- 7. To construct a rectangle equal in area to a given triangle
- 8. To find a fourth proportional to three given lines.
- 9. On a given line to construct a rectangle which shall be equal to a given rectangle.
- 10. To construct a square that shall be equal in area to a given parallelogram.

BOOK V.

PLANES AND THEIR ANGLES.

DEFINITIONS.

- 1. A PLANE is a surface such that a straight line connecting any two of its points will lie entirely in the surface.
- 2. A straight line is PERPENDICULAR TO A PLANE when it is perpendicular to every line of the plane passing through its foot. The *foot* is the point where the line meets the plane.

Reciprocally, the plane is also perpendicular to the line.

3. A straight line is PARALLEL TO A PLANE when it cannot meet the plane, however far both be produced.

Reciprocally, the plane is also parallel to the line.

- 4. Two Planes are Parallel when they cannot meet, however far both be produced.
- 5. When two planes meet, they form a line, which is called their LINE OF INTERSECTION.
- 6. A DIEDRAL ANGLE is the divergence of two planes.
 The line in which the planes intersect is called the edge of the angle; the planes

are called the faces of the angle.

A diedral angle is measured by the angle formed by two lines, one in each plane and perpendicular to the edge at the same

point. Thus, the diedral angle in the margin is measured by the angle ACB.

7. A POLYEDRAL ANGLE is the divergence of three or more planes proceeding from a common point.

The common point is called the vertex of the angle; the planes are its faces; the intersection of the planes, its edges.

- 8. A TRIEDRAL ANGLE is a polyedral angle of three faces.
- 9. Two planes are Perpendicular to each other when their diedral angle is a right angle.

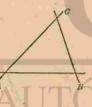

ANALYSIS.—This Book treats of planes, the lines and angles formed by their intersection. It is not so valuable in itself as the other Books of Geometry, and much less interesting. Its object is to prepare for the Book which immediately follows it.

THEOREM I.

Through three points not in the same straight line, one plane can be passed, and but one.

Let A, B, and C be the three points; then can one plane be passed through them.

For, join two of the points, as A and C, by the line AC. Pass a plane through AC, and turn it around AC until it contains the point B_j it will then pass through the three points A, C, and B. If now the plane be turned about AC,

it will no longer contain the point B; hence, only this one plane can be passed through the three points. Therefore, etc.

- Cor. 1. Since only one plane can be passed through three points, three points are said to determine the position of a plane.
- Cor. 2. Two lines which are parallel or which intersect determine the position of a plane.

THEOREM II.

If two planes cut one another, their common section is a straight line.

Let the two planes AB and CD cut one another in the points E and F; then will their common section be a straight line.

For, draw the line EF uniting the two common points E and F of the planes. Now, this line, having two points in the plane AB, will lie wholly in the plane AB (B. I. Def.), and, having two points

in the plane CD, it will lie wholly in the plane CD; hence, the line EF is common to both planes, and must therefore be in their common intersection. Therefore, etc.

THEOREM III.

If from a point without a plane lines be drawn to the plane,

- 1. The perpendicular is the shortest distance from the point to the plane;
- Oblique lines which meet the plane at equal distances from the foot of the perpendicular are equal;
- 3. Of two oblique lines which meet the plane at unequal distances from the foot of the perpendicular, the one which meets it at the greater distance is the longer.

Let A be a point without the plane MN; let AB be a perpendicular to the plane, and let AC, AD, and AE be oblique lines.

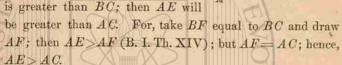

First. AB will be shorter than any oblique line AC. For, through B draw the line BC; then in the triangle ABC, AB is less than AC (B. I. Th. XIV.).

Second. Let AC and AD meet the plane at equal distances

from the point B; then AC will be equal to AD. For, draw BC and BD; then the right-angled triangles ABC and ABD will have BC equal to BD, and the side AB common; hence, the triangles are equal, and AC comple

angles are equal, and AC equals AD.

Third. Let AC and AE meet the plane so that the distance BE is greater than BC; then AE will

Cor. 1. Equal oblique lines drawn from a point to a plane meet the plane at equal distances from the foot of the perpendicular; and of two unequal oblique lines, the greater meets the plane at the greater distance from the foot of the perpendicular.

Cor. 2. The equal oblique lines meet the plane in the circumference of a circle whose centre is B; hence, to draw a perpendicular from a point A to a given plane MN, find any three points, C, D, and F, of the plane equally distant from A, then find the centre of the circumference passing through these points; then AP will be the perpendicular required.

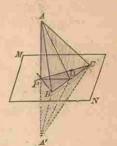

THEOREM IV.

If a straight line is perpendicular to two straight lines of a plane at the point of their intersection, it is perpendicular to the plane of those lines.

Let AP be perpendicular to PB and PC at the point P; then will it be perpendicular to MN, the plane of those lines. For, let PD be any other straight line of the plane MN

drawn through P. Draw BC, cutting PB, PD, and PC in B, D, and C; produce AP making PA' = AP; and draw AB,

AD, AC, A'B, A'D and A'C. Then, since BP and CP are perpendicular to AA' at its middle point, AB equals A'B, and AC equals A'C, and the triangles ABC and A'BC are equal (B. I. Th. IX.), and also AD equals A'D; whence PD is perpendicular to AA' (B. I. Th. XIV. C. 3). Hence, AP is perpendicular to any line passing

through its foot; it is, therefore, perpendicular to the plane MN.

Cor. Only one perpendicular can be erected to a plane from a point of the plane.

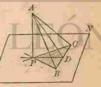

THEOREM V.

If from the foot of a perpendicular to a plane a line is drawn at right angles to any line of the plane, and the point of intersection is joined with any point of the perpendicular, the last line will be perpendicular to the line of the plane.

Let AP be a perpendicular to the plane MN, P its foot, BC the given line, and A any point of

AP; draw PD perpendicular to BC, and join the points A and D; then will AD be perpendicular to BC.

For, lay off BD equal to DC, and draw PB, PC, AB, and AC. Since PD

is perpendicular to BC, and DB equals DC, PB equals PC (B. I. Th. XIV.); hence, in the triangles APB and APC, AB equals AC. Therefore the line AD, having two points, A and D, equally distant from B and C, is perpendicular to BC (B. I. Th. XIV. C. 3).

BOOK V.

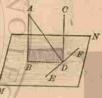

Cor. The line BC is perpendicular to the plane of the triangle APD, because it is perpendicular to AD and PD at the point D (Th. IV.).

THEOREM VI.

If one of two parallels is perpendicular to a plane, the other is also perpendicular to the plane.

Let AB and CD be two parallel lines, and let AB be perpendicular to the plane MN; then will CD also be perpendicular to MN.

For, pass a plane through the parallels cutting MN in BD; draw AD, and in the plane MN draw EF perpendicular to BD at the point D. Then, EF is perpendicular to the plane ABDC (Th.

V. C.); hence, the angle EDC is a right angle; but CDB is a right angle, since CD is parallel to AB (B. I. Th. III. C.); hence, CD is perpendicular to the two lines BD and EF at their point of intersection; it is, therefore, perpendicular to the plane MN (Th. IV.). Therefore, etc.

Cor. 1. Conversely.—Two lines which are perpendicular to the same plane are parallel. For, suppose the two lines AB and CD to be perpendicular to the plane MN; then, if they are not parallel, draw from the point D a line which is parallel to BA; this line will be perpendicular to MN (Th. VI.); we shall then have two perpendiculars to the plane MN from the same point, which is impossible (Th. IV. C.); therefore, AB and CD are parallel.

Cor. 2. Two lines parallel to a third line are parallel to each other. Let the two lines A and B be parallel to a third line ; pass a plane perpendicular to C, it will be perpendicular

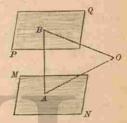

to both A and B (Th. VI.); hence, A and B, being perpendicular to the same plane, are parallel (Th. VI. C. 1).

THEOREM VII.

If two planes are perpendicular to the same straight line, they are parallel.

Let the two planes MN and PQ be perpendicular to the straight line AB; then will they be parallel.

For, if they are not parallel, they will meet in some point O. From O draw the lines OA and OB; then, since OA lies in the plane MN, it will be perpendicular to AB at A (D.2); and since OB lies in the plane PQ, it will be perpendicular to AB

at B. Hence, we have two perpendiculars drawn from the same point to the same straight line, which is impossible (B. I. Th. XIV. C. 1); consequently, the planes cannot meet, and are, therefore, parallel.

THEOREM VIII.

If a plane meet two parallel planes, the lines of intersection are parallel.

Let the plane AC intersect the two parallel planes MN and PQ; then will AB and CD be parallel.

For, if the lines AB and CD are not parallel, since they lie in the same plane, they will meet if sufficiently produced, and, consequently, the planes MN and PQ will meet; but the planes cannot meet, since they are parallel; hence, the lines AB and CD cannot meet; they are, therefore, parallel.

Cor. Parallel lines included between parallel planes are equal. For, the opposite sides of the figure AC being parallel, it is a parallelogram, and hence AD equals BC.

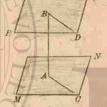

THEOREM IX.

If a straight line is perpendicular to one of two parallel planes, it is perpendicular to the other also.

Let MN and PQ be two parallel planes, and let the line AB be perpendicular to PQ; then will it

also be perpendicular to the plane MN.

For, pass any plane through AB; the intersections AC and BD will be parallel (Th. VIII.); since AB is perpendicular to PQ, it will be perpendicular to BD (D.2), and since BD and AC are parallel,

it will be perpendicular to AC (B. I. Th. III. C.); hence, BA, being perpendicular to any line of the plane MN passing through its foot, is perpendicular to the plane MN. Therefore, etc.

THEOREM X.

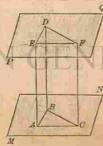

If two angles not in the same plane have their sides parallel and lying in the same direction, the angles will be equal and their planes parallel.

Let BAC and DEF be two angles not in the same plane, having their sides respectively parallel

and lying in the same direction; then will these angles be equal and their planes parallel.

Take ED equal to AB, and EF equal to AC, and draw BC, DF, AE, BD, and CF.

First. The angles BAC and DEF will be equal.

For, since AC and EF are equal and parallel, the figure ACFE is a parallelogram (B. I. Th. XVII.), and AE and CF are equal and parallel. Since AB and ED are equal and parallel, ABDE is a parallelogram, and AE and BD are equal and parallel; hence, BD and CF are equal and parallel (Th. VI. C. 2), and, consequently, DF is equal and parallel to BC. Hence, the triangles ABC and EDF have their corresponding sides equal; they are, therefore, equal, and the angle DEF equals the angle BAC.

Second. The planes are parallel.

For, three lines which intersect determine the position of a plane; and since the three sides of the triangles are respectively parallel, their planes must be parallel.

Cor. If three straight lines not in the same plane are equal and parallel, the triangles formed by joining the extremities of these lines will be equal, and their planes parallel. This is readily proved; let the pupil show it.

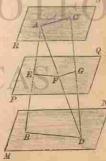

THEOREM XI.

If two straight lines are cut by three parallel planes, they will be divided proportionally.

Let the lines AB and CD be cut by the parallel planes MN, PQ, and RS, in the points A, E, S, and C, G, D; then will

AE:EB::CG:GD.

For, draw the line AD, meeting the plane PQ in F; draw also AC, EF, FG, and BD. Now, since the planes MN and PQ are parallel, EF is parallel to BD (Th. VIII.); and since PQ and RS are parallel, AC is parallel to FG. Hence (B. III. Th. IX.), we have,

THEOREM XIII.

The sum of the plane angles which form any polyedral angle, is less than four right angles.

Let S be the vertex of a polyedral angle formed by the plane angles ASB, BSC, CSD, etc.; then will the sum of these plane angles be less than four right angles.

For, pass a plane cutting the edges in the points A, B, C, D, E, and F, and the faces in the lines AB, BC, etc. From any point, O, in the polygon thus formed,

draw the lines OA, OB, OC, etc. We then have two sets of triangles, one set having their vertices at S, the other at O, and both having the common bases AB, BC, etc.

Now, the sum of the angles of the upper set of triangles is equal to the sum of the angles of the lower set of triangles, since both sets consist of the same number of triangles. But the sum of the angles SBA and SBC is greater than ABC, or ABO + OBC (Th. XII.); and also SCB + SCD is greater than OCB + OCD; and so on with the other angles at D, E, etc. Hence, the sum of all the angles at the bases of the upper set of triangles is greater than the sum of all the angles at the bases of the lower set of triangles; therefore, the sum of the angles at S must be less than the sum of the angles at O. But the sum of the angles at O is equal to four right angles (B. I. Th. II. C. 2); hence, the sum of the angles at S is less than four right angles. Therefore, etc.

Scholium. This proposition supposes that the polyedral angle is convex; if it were not, the sum of the plane angles would be unlimited.

AE : EB :: AF : FD; and also, AF : FD :: CG : GD.

Hence, from the principles of proportion, we have,

AE:EB::CG:GD.

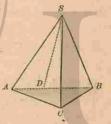

Therefore, etc.

THEOREM XII.

Either angle of the three plane angles which form a triedral angle, is less than the sum of the other two.

Let the triedral angle whose vertex is S be formed by the three plane angles ASC, ASB, and CSB; then will any one of these be less than the sum of the other two.

If the angle considered is less than either of the other two, it is evidently less than their sum. Suppose, however, the angle greater than either of the other two, and let ASB be that angle. In the plane ASB make the angle BSD equal to BSC, draw the line AB

at pleasure, make SC equal to SD, and draw AC and BC.

In the two triangles BSC and BSD, BS is common, CS equals DS, and the angle BSC equals BSD by construction; hence, the triangles are equal, and BD equals BC. Now (B. I. A. 10, C.),

AD + DB < AC + BC

And, taking away the equals DB and BC, we have,

AD < AC

Hence (B. I. Th. VIII. C.), we have,

angle ASD < angle ASC;

and, adding the equal angles DSB and CSB, we have, angle ASB < angle ASC + angle CSB.

Therefore, etc.

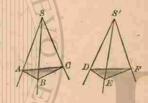

THEOREM XIV.

If the three face angles of a triedral angle are respectively equal, the triedral angles are either equal or symmetrical.

Let S and S' be the vertices of two triedral angles in which ASB equals DS'E, BSC = ES'F and ASC = DS'F; then the diedral angles are respectively equal, and the triedral angles are either equal or symmetrical.

For, on SB take any point B, and in the faces ASB and

BSC draw the lines BA and BC perpendicular to SB; then the angle ABC will measure the diedral angle of the faces ASB and BSC (Def. 6). On S'E lay off S'E equal to SB, and on the faces DSE and ES'F draw

DE and EF perpendicular to S'E; then the angle DEF will measure the diedral angle of the faces DS'E and ES'F.

The right-angled triangles SBA and S'ED are equal, since SB=S'E and ASB=DS'E; hence, AB equals DE and AS equals DS'. In a similar way it may be shown that BC equals EF and CS equals FS'. Hence, the triangles ASC and DS'F have their sides respectively equal; and ASC equals DS'F by hypothesis; therefore AC equals DF. Hence, the triangles ABC and DEF have their sides respectively equal, and consequently their corresponding angles are equal. Hence the angle ABC, which measures the diedral angle of the planes ASB and ASC, is equal to the angle ASC, which measures the diedral angle of the planes ASC and ASC equals ASC. In the same way it may be shown that the other diedral angles are respectively equal.

Now, if the face angles of these triedral angles are similarly placed, the triedral angles may be applied to each other

and they will coincide; if, however, the face angles are not similarly placed, the triedral angles will not coincide, but are then said to be *symmetrical*. Therefore, etc.

Scholium. Polyedral angles are said to be symmetrical when, having the same number of face angles, these angles and the successive diedral angles are respectively arranged in a reverse order.

THEOREMS FOR ORIGINAL THOUGHT.

- 1. Prove that but one plane can be passed through a given point perpendicular to a given line.
- 2. If a line is perpendicular to a plane, every plane passed through the line is perpendicular to that plane.
- 3. If two planes are perpendicular to each other, a line drawn in one of them perpendicular to their intersection is perpendicular to the other.
- 4. If two planes which cut each other are both perpendicular to a third plane, their intersection is perpendicular to that plane.
- Prove that through a given line of a given plane, only one plane perpendicular to the given plane can be passed.
- Prove that through a line parallel to a given plane, only one plane perpendicular to the given plane can be passed.
- 7. If two planes which intersect contain two lines parallel to each other, the intersection of the planes will be parallel to the lines.
- 8. If a line is parallel to one plane and perpendicular to another, these two planes are perpendicular.
- 9. If two planes are parallel to a third, they are parallel to each other.
- 10. Only one plane can be drawn through a given point parallel to a given plane.
- 11. If two lines are parallel in space, and planes be passed through them perpendicular to a third plane, the two planes will be parallel.

PROBLEMS.

The following problems are easily solved from the principles already presented.

- 1. To erect a perpendicular to a given plane at a given point of the plane. (See Prop. III.)
- 2. To construct a plane parallel to a given plane.

UNIVERSIDAD AU

- 3. To construct a plane perpendicular to a given plane intersecting it in a given straight line.
- 4. To draw a line from a given point of a plane making any given angle with the plane.
- 5. To draw a plane intersecting a given plane and making any given angle with it.

BOOK VI.

POLYEDRONS.

DEFINITIONS.

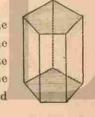

1. A POLYEDRON is a volume bounded by polygons.

The bounding polygons are called the faces of the polyedron; the lines in which the faces meet are called edges; and the points in which the edges meet are called vertices of the polyedron.

2. A PRISM is a polyedron, two of whose faces are equal

polygons, having their homologous sides parallel; the other faces are parallelograms.

The equal polygons are called bases of the prism; one, the upper base; the other, the lower base. The parallelograms constitute the lateral or convex surface of the prism; the intersections of the lateral faces are called lateral edges.

3. The ALTITUDE of a prism is the perpendicular distance between its bases.

4. A RIGHT PRISM is one whose lateral edges are perpendicular to the bases. In a right prism, each lateral edge is equal to the altitude.

5. An Oblique to the bases. Each lateral edge is, consequently, greater than the altitude.

6. A prism is named from its bases. A triangular prism is one whose bases are triangles; a quadrangular prism is one whose bases are quadrilaterals; and so on.

PROBLEMS.

The following problems are easily solved from the principles already presented.

- 1. To erect a perpendicular to a given plane at a given point of the plane. (See Prop. III.)
- 2. To construct a plane parallel to a given plane.

UNIVERSIDAD AU

- 3. To construct a plane perpendicular to a given plane intersecting it in a given straight line.
- 4. To draw a line from a given point of a plane making any given angle with the plane.
- 5. To draw a plane intersecting a given plane and making any given angle with it.

BOOK VI.

POLYEDRONS.

DEFINITIONS.

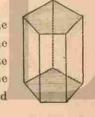

1. A POLYEDRON is a volume bounded by polygons.

The bounding polygons are called the faces of the polyedron; the lines in which the faces meet are called edges; and the points in which the edges meet are called vertices of the polyedron.

2. A PRISM is a polyedron, two of whose faces are equal

polygons, having their homologous sides parallel; the other faces are parallelograms.

The equal polygons are called bases of the prism; one, the upper base; the other, the lower base. The parallelograms constitute the lateral or convex surface of the prism; the intersections of the lateral faces are called lateral edges.

3. The ALTITUDE of a prism is the perpendicular distance between its bases.

4. A RIGHT PRISM is one whose lateral edges are perpendicular to the bases. In a right prism, each lateral edge is equal to the altitude.

5. An Oblique to the bases. Each lateral edge is, consequently, greater than the altitude.

6. A prism is named from its bases. A triangular prism is one whose bases are triangles; a quadrangular prism is one whose bases are quadrilaterals; and so on.

7. A PARALLELOPIPEDON is a prism whose bases are parallelograms.

A RECTANGULAR PARALLELOPIPEbon is a right parallelopipedon with rectangular bases. A cube is a rectangular parallelopipedon, all of whose faces are equal squares.

8. A PYRAMID is a polyedron bounded by a polygon, and by triangles meeting at a common point.

The polygon is called the base of the pyramid; the triangles, its lateral or convex surface; and the point where the triangles meet, its vertex.

9. Pyramids are named from their bases; thus, we have triangular, quadrangular, pentangular, etc. pyramids, as the bases are triangles, quadrilaterals, pentagons, etc.

10. The ALTITUDE of a pyramid is the perpendicular distance from the vertex to the plane of the base.

11. A RIGHT PYRAMID is one whose base is a regular polygon, and in which a perpendicular from the vertex to the base passes through the centre of the base. This perpendicular is called the axis of the pyramid.

12. The SLANT HEIGHT of a right pyramid is the perpendicular distance from its vertex to any side of the base.

13. A FRUSTUM OF A PYRAMID is the part of a pyramid included between its base and a plane cutting the pyramid parallel to the base.

14. The ALTITUDE of a frustum of a pyramid is the perpendicular distance between its bases.

right pyramid is that portion of the slant height of the pyramid included between the bases of the frustum.

16. SIMILAR POLYEDRONS are those which are bounded by the same number of similar polygons, similarly placed. Parts which are similarly placed are homologous, whether faces, angles, or edges.

17. The DIAGONAL of a polyedron is a line joining the vertices of any two polyedral angles not in the same face.

18. The VOLUME of a-polyedron is its numerical value, expressing how many times it contains some other polyedron as a unit.

19. A RIGHT SECTION of a prism is a section perpendicular to its lateral edges. An *oblique* section is one oblique to its lateral edges.

20. A TRUNCATED PRISM is a portion of the prism included between either base and an oblique section of the prism.

Analysis.—This book treats of prisms, pyramids, and frustums. The object is to find the surface and volume of these polyedrons, and the relation of those which are similar. Their surface is readily determined by finding the area of the polygons which form their faces. In finding their volumes, we begin with the rectangular parallelopipedon, assuming for a unit of measure a cube whose edge is a unit of measure of the edges of the parallelopipedon. From the volume of a rectangular parallelopipedon we pass to that of any parallelopipedon, thence to the volume of a triangular prism, and from this to that of any prism. The division of a triangular prism into three equal parts gives the volume of a triangular pyramid, from which we pass to the volume of any pyramid, and also of any frustum.

THE PRISM.

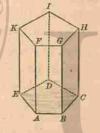

THEOREM I.

The convex surface of a right prism is equal to the perimeter of the base multiplied by the altitude.

Let ABCDE—K be a right prism; then will its convex surface be equal to

$$(AB + BC + CD + DE + EA) \times AF$$
.

For, the convex surface of the prism is equal to the sum of all the rectangles AG, BH, CI, etc. Now, the altitude of each of these rectangles is equal to the altitude of the prism, and the area of each rectangle is equal to its base multiplied by its altitude; hence, the convex

surface, which is the sum of the areas of these rectangles, is equal to

$$(AB + BC + CD + DE + EA) \times AF;$$

or, the perimeter of the base multiplied by the altitude. Therefore, etc.

Cor. If two right prisms have the same altitude, their convex surfaces are to each other as the perimeters of their bases.

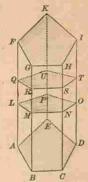

THEOREM II.

If a prism be cut by parallel planes, the sections formed will be equal polygons.

Let the prism ABCDE-K be cut by the parallel planes

LO and QT; then will the sections LO and QT be equal polygons.

For, LM and QR are parallel, being the intersections of the two parallel planes with ABGF (B. V. Th. VIII.); these lines LM and QR are also equal, since they are parallels included between the two parallels AF and BG (B. I. Th. XV. C. 2.). For a like reason, MN is equal and parallel to RS, NO to ST, OP to TU, etc.; hence, the angle LMN is equal to the angle QRS, MNO to RST, etc. (B. V. Th. X.); therefore, the sections are equal polygons.

Cor. Every section of a prism parallel to the base is equal to the base.

THEOREM III.

Two prisms are equal if three faces, including a triedral angle of one, are respectively equal to three faces similarly placed, including a triedral of the other.

Let the three faces of the triedral angles A and L of the prisms ABCDE - F and LMNOP - Q be equal and similarly placed; then will the prisms be equal.

For, place the base ABCDE on its equal LMNOP; then, since the triedral angles A and L are equal (B. V. Th. XIV.), they will coincide when applied to each other, the face AG will coincide to each other.

the upper base of the other prism; hence also the planes of their bases will coincide, and, since these bases are equal, they will coincide throughout; consequently, all the lateral faces of the two prisms will coincide, each to each, and the prisms will coincide throughout, and are therefore equal. Therefore, etc.

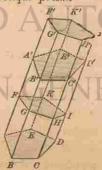

Cor. 1. Two right prisms are equal if they have equal bases and equal altitudes. For, if the faces are similarly placed, the prisms will coincide when applied to each other. If the faces are not similarly placed, by inverting one prism the faces will be similarly placed, and the prisms may be applied to each other and will coincide.

Cor. 2. Two truncated prisms are equal if three faces including a triedral angle of one are respectively equal to three faces including a triedral angle of the other. For, the above demonstration will apply whether the upper bases are parallel to the lower bases or are inclined to them, as they are in a truncated prism.

THEOREM IV.

An oblique prism is equivalent to a right prism whose base is equal to a right section of the oblique prism, and whose altitude is equal to a lateral edge of the oblique prism.

Let ABCDE-A' be an oblique prism. At any point F, in the edge AA', pass a plane perpendicular to AA', forming the right section FGHIK. Produce AA' to F', making FF' equal to AA', and through F' pass a second plane perpendicular to the edge AA', intersecting all the faces of the prism produced, and forming another right section,

F'G'H'I'K', parallel and equal to FGHIK. The prism FGHIK - F' is a right prism whose base is the right section FGHIK, and whose altitude, FF', is equal to the lateral edge of the oblique prism.

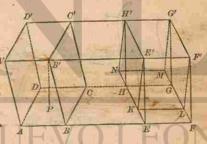

Now, the truncated prism ABCDE - F is equal to the truncated prism A'B'C'D'E' - F' (Th. III. Cor. 2); if to each of these equal prisms we add the volume FGHIK - A', we shall have the oblique prism ABCDE - A', equivalent to the right prism FGHIK - F'. Therefore, etc.

THEOREM V.

Any parallelopipedon is equivalent to a rectangular parallelopipedon having the same altitude and an equivalent base.

Let ABCD - D' be any oblique parallelopipedon whose base is ABCD and altitude B'P. Produce the edges, AB,

DC, A'B', and D'C'; on AB produced take EF equal to AB, and through E and F pass planes perpendicular to the produced edges, forming the parallelopipedon EFGH—H'.

This parallelopipedon, regarding EE'H'H as the base and EF the altitude, is a right prism, and is equivalent to the oblique parallelopipedon ABCD-A' (Th. IV.).

Again, from E' and H' let fall the perpendiculars E'K and H'N to EH produced, and from F' and G' let fall the perpendiculars F'L and G'M to FG produced, and draw LK and MN; then KLMN-H' will be a rectangular parallelopipedon whose base is KLMN and altitude E'K equal to B'P.

Thus, the rectangular parallelopipedon KLMN-H' is equivalent to the oblique parallelopipedon EFF'E'-H (Th. IV.); but this parallelopipedon EFF'E'-H, which, with EE'H'H as a base, is a right parallelopipedon, is equivalent to the parallelopipedon ABCD-D' (Th. IV.); hence, ABCD-D' is equivalent to the right parallelopipedon KLMN-H'. Also, the base KM is equal to the base E'G', and hence to its equal EG, which is equivalent to the base AC; hence KM is equivalent to AC. Therefore, etc.

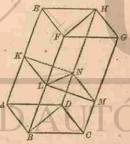

THEOREM VI.

The plane passed through two diagonally opposite edges of a parallelopipedon divides the parallelopipedon into two equivalent triangular prisms.

Let ABCD-E be any parallelopipedon, and let a plane be passed through its opposite edges BF and DH; then will the triangular prisms ABD-H and

BCD - H be equivalent.

For, let KLMN be any right section of the parallelopipedon made by a plane perpendicular to the edge AE; the intersection, LN, of this plane with the plane BH is the diagonal of the parallelogram KLMN, and divides the parallelogram into

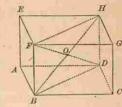

two equal triangles, LMN and KLN. The oblique prism ABD-H is equivalent to a right prism whose base is the triangle KLN and whose altitude is AE (Th. IV.); and the oblique prism BCD-H is equivalent to a right prism whose base is the triangle LMN and altitude AE; but the two right prisms are equal (Th. III. C. 1); hence, the two oblique prisms are equivalent to each other. Therefore, etc.

THEOREM VII.

The opposite faces of a parallelopipedon are equal and parallel.

Let ABCD—H be a parallelopipedon; then will its opposite faces be equal and parallel.

For, the bases are equal and parallel, by the definition of a parallelopipedon. Also, BC is equal and parallel to AD, since the figure ABCD is a parallelogram, and, for a similar reason, BF and AE are equal and

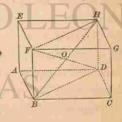

parallel; consequently, the angles EAD and FBC are equal, and their planes parallel (B. V. Th. X.), and, therefore, the parallelograms BG and AH are equal (B. I. Th. XV. C. 3). In a similar manner it may be shown that the faces AF and DG are equal and parallel. Therefore, etc.

Cor. 1. Any two opposite faces of a parallelopipedon may be taken as the bases.

Cor. 2. The diagonals of a parallelopipedon bisect each other.

Draw the diagonals FD and BH; draw also BD and FH; then, since BF and HD are equal and parallel, the

figure BDHF is a parallelogram; hence, the diagonals FD and BH bisect each other at O (B. I. Th. XVIII.). In the same manner it may be shown that either of these and any other diagonal bisect each other; hence, all the diagonals bisect each other.

Cor. 3. In a rectangular parallelopipedon, the square of either diagonal equals the sum of the squares of the three

113

edges which meet at the same vertex. Let the pupil show it; that $\overline{B}\overline{H}^2 = \overline{B}\overline{C}^2 + \overline{D}\overline{C}^2 + \overline{D}\overline{H}^2$.

THEOREM VIII.

The volume of a rectangular parallelopipedon is equal to the product of its base and altitude.

Let ABCD-H be a rectangular parallelopipedon; then will its volume be equal to its base ABCD multiplied by its altitude AE.

Suppose AK to be a common unit of measure of the three sides AB, AD, and AE, and suppose it to be contained 4 times in AB, 3 times in AD, and 5 times in AE; then divide AB into 4 equal parts, AD into 3, and AE into 5 equal parts, and pass planes through the points of division parallel to the faces of the parallelopipedon. The

F F C

parallelopipedon will thus be divided into equal cubes, equal since their sides are equal and their angles are equal, all being right angles.

Now, the number of these little cubes upon the base is equal to the number of surface units in the base, and the whole number of cubes in the parallelopipedon is equal to the number upon the base multiplied by the number of layers, and the number of layers is the same as the number of units in the altitude; hence, the number of cubic units in the parallelopipedon is equal to the base multiplied by the altitude. Now, this is evidently true whatever be the size of the linear unit; hence, it is true when the linear unit is exceedingly small, and, consequently, when it is infinitely small, as it must be when the three sides are

incommensurable. Therefore, the volume of a rectangular parallelopipedon is equal to the product of its base and altitude.

Cor. 1. It is evident that the number of cubic units upon the base is equal to the number of rows multiplied by the number in each row; that is, the length of the base multiplied by its breadth; hence, the volume of a rectangular parallelopipedon equals the product of its length, breadth, and altitude, or the product of its three dimensions.

Cor. 2. Any two rectangular parallelopipedons are to each other as the products of their bases and altitudes, or as the products of their three dimensions.

Cor. 3. When their bases are equal, they are to each other as their altitudes; when their altitudes are equal, they are to each other as their bases.

THEOREM IX.

The volume of any parallelopipedon is equal to the product of its base and altitude.

Let ABCD - E be any parallelopipedon whose base is ABCD and altitude H; then will its volume be equal to the base ABCD

multiplied by the altitude H.

For, the parallelopipedon ABCD-E is equivalent to a rectangular parallelopipedon having the same altitude and an equivalent base (Th. V.); but the volume of such a rectangular parallelopipedon is equal to the product of its

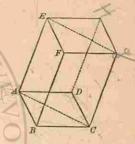

pipedon is equal to the product of its base and altitude (Th. VIII.); hence, the volume of the parallelopipedon ABCD - E is equal to the product of its base and altitude. Therefore, etc.

THEOREM X.

The volume of any prism is equal to the product of its base and altitude.

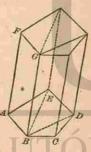

1st. Let ABC - E be a triangular prism. This prism is

half the parallelopipedon constructed on its edges AB, BC, and BF (Th. VI.). The volume of this parallelopipedon is equal to its base ABCD multiplied by its altitude (Th. IX.); hence, the volume of the triangular prism ABC - E is equal to its base ABC, the half of ABCD, multiplied by its altitude.

2d. Let ABCDE - F be any prism. Divide it into triangular prisms by passing planes through any lateral edge BG; these prisms will have a common altitude, the altitude of the prism.

The volume of any triangular prism, ABE - F, is equal to the product of its base and altitude, as just shown; hence, the volume of the prism ABCDE - F, which is the sum of these triangular prisms, is equal to its base, which is the sum of the bases of the triangular prisms, multiplied by its altitude. Therefore, etc.

Cor. 1. Prisms having equivalent bases and equal altitudes are equivalent.

Cor. 2. Any two prisms are to each other as the products of their bases and altitudes.

Cor. 3. Prisms having equal altitudes are to each other as their bases.

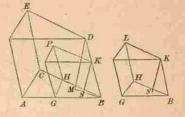

Cor. 4. Prisms having equal bases are to each other as their altitudes.

THEOREM XI.

Similar triangular prisms are to each other as the cubes of their homologous edges.

Let ABC-E and GBH-L be two similar triangular

prisms; then will they be to each other as the cube of any two homologous edges AB and GB.

For, since the two prisms are similar, the faces containing the triedral angles B and B are respectively

similar; therefore, the prism GBH-L being applied to the prism ABC-E will take the position GBH-P. From D draw DM perpendicular to the base, and from K draw KN perpendicular to the base; then the two triangles DMB and KNB must be similar, since they are mutually equiangular.

Now, since the bases are similar, we have (B. III. Th. XVI.),

base ABC: base GBH: $\overline{AB^2}$: $\overline{GB^2}$;

and, since the triangles *DMB* and *KNB* are similar, and also the parallelograms *AD* and *GK*, we have,

DM:KN::DB:KB::AB:GB.

Multiplying together the corresponding terms of the first and last couplets of these two proportions, we have,

base $ABC \times DM$; base $GBH \times KN$: AB^3 : GB^3 .

But $base\ ABC\times DM$ is the volume of the prism ABC-E, and $base\ GBH\times KN$ is the volume of the prism. GBH-L; hence, the prisms are to each other as \overline{AB} to \overline{GB} . Therefore, etc.

Cor. 1. Any two similar prisms are to each other as the cubes of their homologous edges.

For, since the prisms are similar, their bases are similar, and may, therefore, be divided into the same number of similar triangles, similarly situated (B. III. Th. XVII.); hence, each prism may be divided into the same number of similar triangular prisms. But these triangular prisms are to each other as the cubes of their homologous edges; hence, the polygonal prisms which are respectively the sum of these triangular prisms must be to each other as the cubes of their homologous edges.

Cor. 2. Similar prisms are to each other as the cubes of their altitudes, or as the cubes of any other homologous lines.

THE PYRAMID.

THEOREM XIL

The convex surface of a right pyramid is equal to the perimeter of the base multiplied by one-half of the slant height.

Let ABCDE - S be a right pyramid, and SH the slant height; then will the convex surface be equal to the perimeter AB + BC + CD + DE + EA multiplied by $\frac{1}{2}$ of SH.

Draw SO perpendicular to the base; then, from the definition of a right pyramid, O is the centre of the base; consequently, the distances AO, BO, CO, etc. are all equal, and therefore the edges SA, SB, SC, etc., are all equal (B. V. Th. III.); and, since the sides AB, BC, etc., are all equal, the triangles SAB, SBC, etc. are all equal, and

their altitudes, which is the slant height of the pyramid, are equal.

Now, the area of each triangle is equal to its base multiplied by one-half of its altitude; hence, the sum of the areas of these triangles, which is the convex surface of the pyramid, equals the sum of their bases into one-half of the slant height SH; that is, the convex surface of the pyramid equals

 $(AB + BC + CD + DE + EA) \times \frac{1}{2}SH.$

Therefore, etc.

THEOREM XIII.

If a pyramid be cut by a plane parallel to the base;

1. The edges and altitude will be divided proportionally.

2. The section will be a polygon similar to the base.

Let the pyramid S-ABCDE be cut by a plane GHIKL parallel to the base; then will the edges SA, SB, SC, etc., with the altitude SO, be divided proportionally, and the section GHIKL

will be similar to the base.

First. Since the planes ABCDE and

GHIKL are parallel, the intersections

AB and GH are parallel (B.V. Th.VIII.);

for the same reason, BC is parallel to

HI, and BO to HP. Hence, we have

(B. III. Th. IX. C. 1),

SA: SG:: SB: SH;

and also, SB:SH::SC:SI;and also, SB:SH::SO:SP.

Hence, the edges and altitude are divided proportionally.

Second. Since GH is parallel to AB, and HI to BC, the angle GHI is equal to ABC (B. V. Th. X.); and, for the same reason, each angle of the polygon GHIKL is equal to the corresponding angle of the base; hence, the two polygons are mutually equiangular.

Again, since GH is parallel to AB, we have,

GH:AB::SH:SB;

and, since HI is parallel to BC, we have,

HI:BC::SH:SB.

Hence, from equal ratios, we have,

GH:AB::HI:BC.

In the same manner, it may be shown that all the sides of the two polygons are proportional; hence, the section *GHIKL* is similar to the base *ABCDE* (B. III. D. 6).

THEOREM XIV.

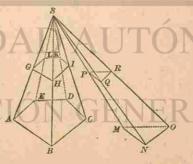

If two pyramids have the same altitude, and their bases in the same plane, the sections made by a plane parallel to their bases are to each other as their bases.

Let S—ABCDE and S—MNO be two pyramids, having

the same altitude, and their bases in the same plane; and let *GHIKL* and *PQR* be sections made by a plane parallel to their bases; then will these sections be to each other as the bases.

For, the polygons ABCDE and GHIKL,

being similar, are to each other as the squares of their sides AB and GH (B. III. Th. XVIII.); but

AB:GH::SA:SG

Hence, $ABCDE: GHIKL:: \overline{SA^2}: \overline{SG^2}$.

For a similar reason,

 $MNO: PQR:: \overline{SM^2}: \overline{SP^2}.$

But (B. V. Th. XI.) we have,

SA:SG::SM:SP:

Hence, ABC

ABCDE: GHIKL:: MNO: PQR.

Therefore, etc.

Cor. 1. If the bases are equal, any two sections parallel to the bases at equal distances from the vertices are equal.

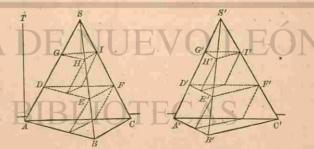

Cor. 2. Any two sections parallel to the base are proportional to the squares of their distances from the vertex.

THEOREM XV.

Two triangular pyramids having equivalent bases and equal altitudes are equal in volume.

Let S - ABC and S' - A'B'C' be two triangular pyramids having equivalent bases ABC and A'B'C' and equal altitudes AT; then will these pyramids be equal in volume.

For, place the bases of the pyramids in the same plane,

divide the altitude, AT, into any number of equal parts, and through the points of division pass planes parallel to the plane of their bases, forming the sections DEF, D'E'F', etc.,

and construct prisms in the two pyramids with these sections as upper bases. Now, the corresponding sections DEF, D'E'F', etc., are equivalent (Th. XIV.); hence, the corresponding prisms, having equivalent bases and equal altitudes, are equivalent (Th. X. C. 1).

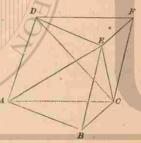

Now, this is true whatever the equal number of inscribed prisms; hence, it is true when the number in each prism becomes indefinitely or infinitely great, in which case they will coincide respectively with the two pyramids; therefore, the pyramids are equal in volume. Therefore, etc.

THEOREM XVI.

A triangular prism may be divided into three equal triangular pyramids.

Let ABC-F be a triangular prism; then may it be divided into three equal triangular pyramids.

Pass a plane through the edge AC and the point E, cutting off the pyramid ABC-E; pass another plane through DE and the

point C, cutting off the pyramid DEF-C; there will remain a pyramid whose base may be regarded as ACD, having its vertex at E. Now, the two pyramids ABC-E and DEF-C are equal in volume, since they have equal bases and equal altitudes (Th. XV.). Regarding the pyramid DEF-C as having the base DCF and vertex at E, it is equal in volume to the pyramid ACD-E, since their bases are equal, being halves of the parallelogram ACFD, and their altitudes are equal, since their bases are in the same plane and vertices at the same point. Hence, the

three pyramids into which the prism is divided are all equal in volume. Therefore, etc.

Cor. 1. A triangular pyramid is one-third of a prism having an equal base and an equal altitude.

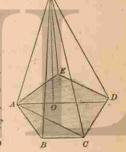

Cor. 2. The volume of a triangular pyramid is one-third of the product of its base and altitude.

THEOREM XVII.

The volume of a pyramid is equal to one-third of the product of its base and altitude.

Let S-ABCDE be a pyramid, and SO the altitude; then will its volume be equal to $ABCDE \times SO$.

Draw the diagonals AC and AD, and pass the planes SAC and SAD through these diagonals and the vertex S; the pyramid will then be divided into triangular pyramids, whose altitudes are equal, being the altitude of the pyramid. Now, the volume of each of these triangular pyramids is equal to its base by one-third of the altitude

(Th. XVI. C. 2); hence, the volume of the pyramid S = ABCDE, which is the sum of these triangular pyramids, is equal to the sum of their bases into one-third of the altitude; that is, base $ABCDE \times \frac{1}{3}SO$. Therefore, etc.

Cor. 1. The volume of a pyramid is one-third of the volume of a prism having an equal base and an equal altitude.

Cor. 2. Pyramids are to each other as the products of their bases and altitudes.

Cor. 3. Pyramids having equal bases are to each other

as their altitudes; pyramids having equal altitudes are to each other as their bases.

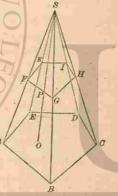

Scholium. The volume of any polyedron may be found by dividing it into triangular pyramids, by passing planes through its vertices.

THEOREM XVIII,

Similar pyramids are to each other as the cubes of their homo-

Let S—ABCDE and S—FGHIK be two similar pyramids; then will they be to each other as the cubes of any two homologous sides AB and FG.

For, since the pyramids are similar, they may be so placed that their homologous angles at the vertex will coincide. Then, since the faces SAB and SFG are similar, AB is parallel to FG; and since SBC and SGH are similar, BC is parallel to GH; hence, the planes of the bases are parallel (B. V. Th. X.).

Draw SO perpendicular to the base ABCDE; it will also be perpendicular to the base FGHIK at some point, P; then (Th. XIII.).

SO: SP:: SB: SG:: AB: FG;

and, consequently,

 $\frac{1}{3}SO: \frac{1}{3}SP::AB:FG.$

But, the bases of the pyramids being similar, we have (B. III. Th. XVIII.),

base ABCDE: base FGHIK:: $\overline{AB^2}$: $\overline{FG^2}$. Multiplying these two proportions, term by term, we have, base $ABCDE \times \frac{1}{3}SO$: base $FGHIK \times \frac{1}{3}SP$: $\overline{AB^3}$: $\overline{FG^3}$.

But, base $ABCDE \times \frac{1}{3}$ SO is equal to the volume of the pyramid S-ABCDE, and base $FGHIK \times \frac{1}{3}$ SP is equal to the volume of the pyramid S-FGHIK; hence, the two pyramids are to each other as the cubes of the homologous edges AB and FG. Therefore, etc.

Cor. Similar pyramids are to each other as the cubes of their altitudes, or as the cubes of any two homologous lines.

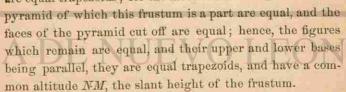

FRUSTUM OF A PYRAMID.

THEOREM XIX.

The convex surface of a frustum of a right pyramid is equal to one-half of the sum of the perimeters of the upper and lower bases, multiplied by the slant height.

Let ABCDE—K be the frustum of a right pyramid, and NM its slant height; then will its convex surface be equal to one-half of the sum of the perimeters of its two bases, multiplied by NM.

The faces forming the convex surface are equal trapezoids; for the faces of the

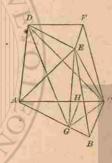

Now, the area of each trapezoid, as ABGF, is equal to $\frac{1}{2}(AB+FG)\times NM$ (B. III. Th. IV.); hence, the area of the convex surface, which is the sum of all the trapezoids, is equal to one-half the sum of the perimeters of the upper and lower bases multiplied by the slant height. Therefore, etc.

THEOREM XX.

The volume of a frustum of a triangular pyramid is equal to the sum of the volumes of three pyramids, whose common altitude is the altitude of the frustum, and whose bases are the lower base of the frustum, the upper base of the frustum, and a mean proportional between the two bases.

Let ABC-F be the frustum of a triangular pyramid. Through the points A, E, C, pass a plane cutting off the

pyramid E-ABC. This pyramid has the altitude of the frustum, and for its base the lower base of the frustum. Through the points D, E, C, passaplane cutting off the pyramid C-DEF This pyramid has the altitude of the frustum, and for its base the upper base of the frustum. The remaining part of the frustum is a pyramid whose base is ACD, with its vertex at E.

Now, draw EG parallel to DA; draw also GD; then the pyramid E-ACD is equal to the pyramid G-ACD, since they have the same base and equal altitudes. But the pyramid G-ACD may be regarded as having AGC for its base, and its vertex at D; it will then have the altitude of the frustum. We will now show that its base AGC is a mean proportional between the two bases of the frustum.

Draw GH parallel to BC; then the triangles AGH and DEF, being similar to ABC, are similar to each other, and, hence, equiangular; and since AG equals DE, the triangle AGH equals DEF (B. I. Th. VII.). Now, AGC is a mean proportional between AGH and ABC (B. III. Th. IX. C. 3); hence, the base of the third pyramid is a mean proportional between the upper and lower bases. Therefore, etc.

Cor. This proposition is true for the frustum of any pyramid. For, since any pyramid is equal to a triangular pyramid having an equal base and equal altitude, by cutting the pyramids with a plane parallel to the base, and removing the upper part, it may be shown that the frustum of any pyramid is equal to the frustum of a triangular pyramid having equal bases and the same altitude; hence, if the proposition is true for triangular frustums, it is true for all frustums.

REGULAR POLYEDRONS.

A REGULAR POLYEDRON is one whose faces are all equal and regular polygons.

There can be five, and only five, regular polyedrons, namely:

1. The TETRAEDRON, or regular pyramid, a polyedron bounded by four equal equilateral triangles.

· 2. The HEXAEDRON, or cube, a polyedron bounded by six equal squares.

3. The OCTAEDRON, a polyedron bounded by eight equal equilateral triangles.

4. The DODECAEDRON, a polyedron bounded by twelve equal regular pentagons.

5. The ICOSAEDRON, a polyedron bounded by twenty equal equilateral triangles.

1st. In the tetraedron the polyedral angle is formed of three equilateral triangles; in the octaedron, of four such triangles; in the icosaedron, of five triangles. The combination of six such angles (each angle being \(^2_3\) of a right angle) gives four right angles, or a plane, and hence no polyedral

angle; and the combination of more than six will not form a convex angle; hence only three regular polyedrons can be formed of triangles.

2d. In the hexaedron the polyedral angle is formed of three squares. The combination of four squares gives a plane, and a greater number would not give a convex angle; hence, but one regular polyedron can be formed of squares.

3d. In the dodecaedron the polyedral angle is formed of three regular pentagons. The combination of more than three such angles (each angle being \(\frac{4}{3} \) of a right angle) exceeds four right angles, and will not give a convex angle; hence, but one regular polyedron can be formed of pentagons.

4th. Three or more angles of a regular hexagon (each angle being 4 of a right angle) exceeds a right angle, and cannot form a convex polyedral angle; and the same is true of the heptagon, octagon, etc.

Therefore, only the five regular polyedrons named above are possible.

PRACTICAL EXAMPLES.

- 1. Required the convex surface of a right prism whose altitude is 14 inches and perimeter of the base 16 inches. Ans. 224 square inches.
- 2. Required the contents of a prism the area of whose base is 24 square feet and altitude 7 feet.

 Ans. 168 cubic feet.
- 3. Required the convex surface of a right pentangular pyramid whose slant height is 18 inches and each side of the base 6 inches.

Ans. 270 square inches.

- 4. Required the volume of the frustum of a square pyramid, the sides of whose bases are 8 and 6 inches, and whose altitude is 12 inches.

 Ans. 592 cubic inches.
- 5. Required the entire surface of a cube whose sides are each 11 inches.

 Ans. 726 square inches.

6. A man wishes to make a cubical cistern whose contents are 373248 cubic inches; how many feet of inch boards will line it?

Ans. 180 square feet.

- 7. What is the side of a cube which contains as much as a volume 20 feet 6 inches long, 10 feet 8 inches wide, and 6 feet 9 inches high?

 Ans. 11.4 feet.
- 8. What is the depth of a cubical cistern which shall contain 1600 gallons, each 231 cubic inches of water? Ans. 5.98 feet.
- 9. Required the dimensions of a cube whose surface shall be numerically equal to its contents.

 Ans. 6 units.
- 10. There are two similar prisms whose lengths are as 7 to 28 respectively; required the relation of their contents.

 Ans. 1: 64.
- 11. Required the contents of a pyramid whose altitude is 20 inches and whose base is a regular hexagon, each side being 6 inches.

Ans. 623.5386 cubic inches.

12. If we pass a plane parallel to the base of the pyramid of the 11th problem, half-way between its vertex and base, required the convex surface and contents of the frustum.

Ans. Vol. = 545.596 cubic inches.

13. A farmer wishes to know what must be the depth of a cubical box which shall contain 100 bushels of grain, each bushel 2150.42 cubic inches.

Ans. 4.9 feet.

THEOREMS FOR ORIGINAL THOUGHT.

- 1. Parallelopipedons having equal bases and equal altitudes are equal in volume.
- 2. The diagonals of a rectangular parallelopipedon are equal.
- 3. If a plane be passed through the opposite edges of a rectangular parallelopipedon, the triangular prisms formed are equal.
- 4. Two prisms having the same base are to each other as their altitudes.
- 5. Two similar pyramids are equal when the base and lateral edge of the one equal the base and lateral edge of the other.
- 6. The surfaces of similar polyedrons are to each other as the squares of their homologous edges

BOOK VII.

THE CYLINDER, THE CONE, AND THE SPHERE.

1. A CYLINDER is a volume which may be generated by the revolution of a rectangle about one of its sides as an axis.

Thus, if the rectangle ABCD be revolved around the side .AB as an axis, it will generate the cylinder in the margin. The line AB is called the axis; the surface described by CD is called the convex surface; the circle BC is the lower base; the circle AD is the upper base.

It is evident that the circle described by the line EF perpendicular to the axis is equal to either base; hence, if a cylinder be cut by a plane parallel to the base, the section will be a circle equal to the base.

2. A CONE is a volume which may be generated by the revolution of a right-angled triangle about one of its sides adjacent to the right angle.

Thus, if the right-angled triangle SBA be revolved around SB as an axis, it will generate the cone ADE-S. The side SB is the axis of the cone; the circle described by AB is the base; the hypothenuse SA is the slant height; the surface generated by SA is the convex surface.

It is evident that the circle described by any line MN perpendicular to the

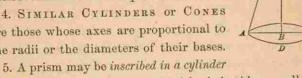

axis is a circle; hence, the section of a cone by a plane parallel to the base is a circle.

3. A FRUSTUM OF A CONE is the part which remains after cutting off the top with a plane parallel to the base.

Thus, ADC-G is the frustum of a cone; FB is its altitude; EA is its slant height. The frustum of a cone may be generated by the revolution of the trapezoid ABFE.

4. SIMILAR CYLINDERS OF CONES are those whose axes are proportional to the radii or the diameters of their bases.

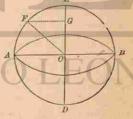

by inscribing similar polygons with their sides parallel in each base, and uniting the vertices of the angles with straight lines. The cylinder is then said to circumscribe the prism.

6. A pyramid may be inscribed in a cone; and a frustum of a pyramid may be inscribed in the frustum of a cone.

7. A SPHERE is a volume bounded by a curved surface, every point of which is equally distant from a point within, called the centre.

The distance from the centre to the circumference is called the radius. The diameter is a line passing through the centre and limited at both extremities by the surface.

- 8. A SPHERICAL SECTOR is a volume generated by the revolution of a sector of a circle about the diameter. Thus, the revolution of ACF will generate a spherical sector.
 - 9. A ZONE is a portion of the surface of a sphere in

cluded between two parallel planes. The bounding lines of the zone are called its *bases*; the distance between the planes is its *altitude*.

10. A Spherical Segment is a portion of the sphere included between two parallel planes.

11. If a semi-circumference be divided into equal arcs, the chords of these arcs form half of the perimeter of an inscribed polygon. The half perimeter is called a regular semi-perimeter.

The figure bounded by the diameter of the semi-circle and the regular semi-perimeter is called a regular semi-polygon. The diameter is called the axis of the semi-polygon.

12. The CYLINDER, the CONE and the SPHERE are the THREE ROUND BODIES of Geometry.

ANALYSIS.—This book treats of the cylinder, the cone, and the sphere. Its object is to find the convex surface and volume of each of these bodies, and also their relation to each other.

The method of treatment consists in regarding these volumes as polyedrous of an infinite number of sides. Thus, the cylinder is regarded as a right prism of an infinite number of sides, the cone as a right pyramid, and the sphere as a polyedron having its centre at the centre of the sphere.

UNIVERSIDAD AUTÓNOM DIRECCIÓN GENERAL I

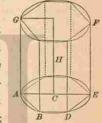

CYLINDER, CONE, AND FRUSTUM.

THEOREM I.

The convex surface of a cylinder is equal to the circumference of its base multiplied by its altitude.

Let ABDE be the base of a cylinder whose altitude is H_j then will its convex surface be equal to circumference $CA \times H$.

For, inscribe in the cylinder a prism whose base is a regular polygon. Now, the convex surface of this prism will be equal to the perimeter of its base multiplied by its altitude (B. VI. Th. I.); and this is true whatever the number of sides;

hence, it is true when the number of sides is infinite. But when the number of sides is infinite, the convex surface of the prism becomes the convex surface of the cylinder, the perimeter of the base of the prism becomes the circumference of the base of the cylinder, and the altitudes being the same, therefore, the convex surface of the cylinder equals the circumference of its base multiplied by its altitude.

Cor. 1. Since the circumference of the base is $2\pi R$, the expression for the convex surface of a cylinder is $2\pi R \times H$.

Cor. 2. The convex surfaces of cylinders which have equal altitudes are to each other as the circumferences of their bases.

THEOREM II.

The volume of a cylinder is equal to the area of its base multiplied by the altitude.

Let ABD-F be a cylinder, whose altitude is H; then will its volume be equal to the area of its base multiplied by its altitude.

For, inscribe in the cylinder a prism whose base is a regular polygon. Now, the volume of this prism is equal to its base multiplied by its altitude (B. VI. Th. IX.), and this is true whatever the number of sides, and therefore true when

the number of sides is infinite. But when the number of sides is infinite, the prism coincides with the cylinder in every respect; hence, the volume of the cylinder is equal to its base multiplied by its altitude. Therefore, etc.

Cor. 1. Since the area of the base is πR^2 , the expression for the volume of a cylinder is $\pi R^2 \times H$.

Cor. 2. Cylinders are to each other as the products of their bases and altitudes. Cylinders having equal bases are to each other as their altitudes; cylinders having equal altitudes are to each other as their bases.

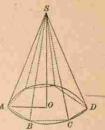

Cor. 3. Similar cylinders are to each other as the cubes of their altitudes, or of the radii of the bases. Let the pupil prove it.

THEOREM III.

The convex surface of a cone is equal to the circumference of its base multiplied by one-half of the slant height.

Let S—ABCD be a cone whose base is ABD and slant height SA; then will its convex surface be equal to the circumference of its base multiplied by one-half of its slant height.

For, inscribe in the cone a right pyramid. The convex surface of this pyramid is equal to the perimeter of its base multiplied by one-half of the slant height (B. VI. Th. XII.); and this is true whatever the number of sides of the base; hence, it is true when the number of sides is infinite.

But when the number of sides is infinite, the pyramid coincides with the cone in every respect; hence, the convex surface of the cone is equal to the circumference of its base multiplied by one-half of the slant height.

Cor. 1. If S represents the slant height, the expression for the convex surface of a cone is $2 \pi R \times \frac{1}{2}S$, or $\pi R \times S$.

THEOREM IV.

The volume of a cone is equal to the base multiplied by onethird of the altitude.

Let S—ABCD be a cone whose base is ABCD and altitude SO; then will its volume be equal to its base multiplied by one-third of its altitude.

For, inscribe in the cone a right pyramid. The volume of this pyramid is equal to the base *ABCD* multiplied by one-third of its altitude *SO* (B. VI. Th. XVII.); and this is true whatever

the number of sides of the base; hence, it is true when the number of sides is infinite. But when the number of sides of the base is infinite, the pyramid becomes the cone; hence, the volume of a cone is equal to its base multiplied by one-third of its altitude. Therefore, etc.

Cor. 1. The expression for the volume of a cone is $\pi R^2 \times \frac{1}{3} H$, or, $\frac{1}{3} \pi R^2 \times H$.

Cor. 2. A cone is one-tnird of a cylinder having an equal base and altitude.

Cor. 3. Cones are to each other as the products of their bases and altitudes; cones having equal bases are to each other as their altitudes; cones having equal altitudes are to each other as their bases.

THEOREM V

The convex surface of a frustum of a cone is equal to one-half of the sum of the circumferences of the upper and lower bases multiplied by the slant height.

Let ABDE-H be a frustum of a cone, OC its altitude, FA its slant height; then will its convex surface be equal to one-half the sum of the circumferences of its two bases multiplied by its slant height.

For, inscribe within the frustum of a cone the frustum of a right pyramid. The convex surface of this frustum is equal to one-half the sum of the peri-

meters of its bases multiplied by the slant height (B. VI. Th. XIX.); and this is true whatever the number of lateral faces; hence, it is true when the number of faces is infinite. But when the number of faces is infinite, the frustum of a pyramid becomes the frustum of a cone, the perimeters of its bases become the circumferences of the bases of the

frustum of the cone, and the slant height of the frustum of a pyramid becomes the slant height of the frustum of a cone; hence, the convex surface of the frustum of a cone equals one-half the sum of the circumferences of its bases multiplied by the slant height.

Cor. The expression for the convex surface of a frustum of a cone is $\frac{1}{2}(2\pi R + 2\pi R') \times S$, where R and R' represent the radii of the bases, and S the slant height.

Scholium. Through L, the middle point of HE, draw LK parallel to EC, and HR and LS perpendicular to EC; now RS = SE (Bk. III. Th. IX.); OH = CR, and KL = CR + RS (Bk. I. Th. XV. C. 2). But CR + RS = SE + OH; hence.

 $KL = \frac{1}{2} (CR + RS + SE + OH)$ or $\frac{1}{2} (CE + OH)$. Multiplying this by 2π , we have,

$$2\pi KL = \frac{1}{2}(2\pi CE + 2\pi OH);$$

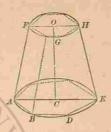

that is, circ. KL equals \(\frac{1}{2} \) of the sum of the circumferences of the two bases; hence, the convex surface of the frustum of a cone, generated by the revolution of the line HE, is equal to the circumference of a circle generated by its middle point into the length of the line.

THEOREM VI.

The volume of the frustum of a cone is equal to the sum of the volume of three cones, having for a common altitude the altitude of the frustum, and for bases the two bases of the frustum and a mean proportional between them.

Let ABDE—H be a frustum of a cone, OC its altitude; then will its volume be equal to the sum of the volumes of three cones whose common altitude is OC, and whose bases are the two bases and a mean proportional between them.

For, inscribe in the frustum the frustum of a right pyramid. The volume of this frustum is equal to the sum of the volumes of three pyramids having the common altitude of the frustum, and whose bases are the two bases of the frustum and a mean proportional between them (B. VI. Th.

XX.); and this is true whatever the number of lateral faces, and, hence, true when the number of faces is infinite. But when the number of lateral faces is infinite, the frustum of the pyramid becomes the frustum of a cone, and the three pyramids become cones; hence, the volume of the frustum of a cone equals the sum of the volumes of three cones, whose common altitude is the altitude of the frustum, and whose bases are the two bases of the frustum and a mean proportional between them.

Cor. The expression for the volume of a frustum of a rone is $(\pi R^2 + \pi r^2 + \pi R \times r) \times \frac{1}{3} H$.

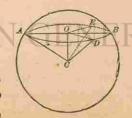

THE SPHERE.

THEOREM VII.

Every section of a sphere made by a plane is a circle.

Let C be the centre of a sphere whose radius is CA, and ADB any section made by a plane; then will this section be a circle.

For, draw CO perpendicular to the section ADB, and draw the lines OD and OE to different points of the

curve ADB; draw also the radii CD and CE. Then, since the radii CD and CE are equal, the lines OD and OE must be equal (B. V. Th. III. C. 1); hence, the section ADB is a circle. Therefore, etc.

Cor. If the plane pass through the centre of the sphere, the radius of the section will be equal to the radius of the sphere. The section is then called a great circle. All other sections are called small circles.

THEOREM VIII.

If a regular semi-polygon be revolved about its axis, the surface generated by the semi-perimeter will be equal to the circumfer ence of the inscribed circle multiplied by the axis.

Let ABCDEF be a regular semi-polygon, AF the axis, ON the radius of the inscribed circle; then will the surface generated by the revolution of the semi-polygon be equal to circ. $ON \times$

AF.

For, from the extremities of any side, as BC, draw BG and CH perpendicular to AF; from N, the middle point of BC, draw NM perpendicular to AF; draw also BL perpendicular to CH. Now, the surface described by BC is equal to CH.

scribed by BC is equal to circ. $MN \times BC$ (Th. V.S.). But, since the triangles BCL and NOM are similar, we have,

 $BC:BL ext{ or } GH::ON:NM::circ. ON:circ. NM;$ hence, circ. NM imes BC = circ. ON imes GH;

that is, the surface generated by BC is equal to the circumference of the inscribed circle multiplied by the altitude GH; and the same may be shown for each of the other sides; hence, the surface described by the entire

semi-perimeter is equal to the circumference of the inscribed circle multiplied by the sum of AG, GH, HI, etc., or the axis AF. Therefore, etc.

Cor. The surface described by any portion of the perimeter, as BCD, is equal to circ. $ON \times GI$.

THEOREM IX.

The surface of a sphere is equal to the circumference of a great circle multiplied by the diameter.

Let ABCDEF be a semicircle, O its centre, and AF its

diameter; then will the surface of the sphere generated by the revolution of the semi-circumference about the diameter be equal to $circ.\ OA \times AF$.

For, inscribe in the semi-circumference a regular semi-polygon. The surface described by the revolution of the polygon is equal to circ. OH × AF (Th. VIII.); and this is true whatever the number of sides;

hence, it is true when the number of sides is infinite, in which case the volume becomes a sphere with the radius OA; hence, the surface of a sphere is equal to circ. $OA \times AF$. Therefore, etc.

Cor. 1. The surface of a sphere is equal to four of its great circles. For, $sur.=circ.\ OA\times 2\ OA$; but $virc.\ OA=2\pi OA$; hence, $sur.=2\pi OA\times 2\ OA$; which gives $sur.=4\pi OA^2$; but πOA^2 is the area of a great circle; hence, $4\pi OA^2$ is the area of four great circles.

Cor. 2. The expression for the surface of a sphere is $4\pi R^2$, or πD^2 , in which R is the radius and D the diameter.

Cor. 3. The surfaces of spheres are to each other as the

squares of their radii or diameters. For, sur. $S = 4 \pi R^2$, and sur. $s = 4 \pi r^2$; hence,

 $S:s::4 \pi R^2:4 \pi r^2$, or $R^2:r^2$.

Cor. 4. The surface of a zone is equal to the circumference of a great circle multiplied by its altitude.

Cor. 5. Zones on the same sphere, or on equal spheres, are to each other as their altitudes. A zone is to the surface of a sphere as the altitude of the zone is to the diameter of the sphere.

THEOREM X.

The volume of a sphere is equal to its surface multiplied by one-third of its radius.

For, conceive a regular polyedron to be inscribed in a sphere; this polyedron may be conceived as consisting of pyramids having their vertices at the centre of the sphere, and for bases the faces of the polyedron. The volume of each of these pyramids is equal to its base multiplied by one-third of its altitude, and, their altitudes being equal, the volume of the polyedron will be equal to the sum of all their bases, which is the surface of the polyedron, multiplied by one-third of the common altitude. Now, the sphere may be regarded as a polyedron consisting of an infinite number of pyramids, having their vertices at the centre of the sphere and their bases at its surface, their altitudes being equal to the radius of the sphere; hence, the volume of a sphere is equal to its surface multiplied by one-third of the radius.

Cor. 1. If we represent the volume of a sphere by vol. S, and the surface by sur. S, we will have,

vol. $S = sur. S \times \frac{1}{2}R$; and since $sur. S = 4 \pi R^2$, we have, vol. $S = 4 \pi R^2 \times \frac{1}{2}R$; which, reduced,

gives, (1) $vol. S = \frac{4}{3} \pi R^8$. But. $R = \frac{1}{3} D$, or $R^3 = \frac{1}{8} D^3$,

Hence, (2) vol. $S = \frac{1}{6} \pi D^3$.

Cor. 2. Spneres are to each other as the cubes of their radii, or diameters.

Cor. 3. The volume of a spherical sector or pyramid is equal to its base multiplied by one-third of the radius.

For the sector or pyramid may be conceived as consisting of an infinite number of pyramids having their vertices at the centre of the sphere, and the volume of the sum of these will be the sum of their bases multiplied by one-third of the radius.

Cor. 4. The volume of a spherical segment of one base and less than a hemisphere, as that generated by ACB revolving about AF, is equal to the volume of the spherical sector ACC minus the volume of the cone formed by OCB.

The volume of a spherical segment of one base and greater than a hemisphere, as AED, is equal to the volume of the spherical sector AOE plus the volume of the cone formed by EDO.

The volume of a spherical segment of two bases, as that generated by BCED, is equal to the volume of the sector, formed by COE, plus the volume of the cones formed by OCB and OED. If the points C and E fall on the same side of the centre, the last cone must be subtracted. The measure is as follows:

Segment BCED = zone $CE \times \frac{1}{3} OC + \pi \overline{BC^2} \times \frac{1}{3} OB + \pi \overline{DE^2} \times \frac{1}{3} OD$.

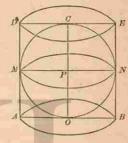

THEOREM XI.

The surface of a sphere is to the entire surface of the circumscribed cylinder, including its bases, as 2 to 3; and their volumes are to each other in the same ratio.

Let AE be a cylinder circumscribed about a sphere whose centre is P_i ; then,

First. The surface of the sphere is to the entire surface of the cylinder as 2 is to 3.

For, the surface of the cylinder equals circumference $AO \times OC$ (Th. I.); that is, the circumference of a great circle of the sphere multiplied by the diameter of the sphere; but this is equal to the surface of a

sphere (Th. IX.); hence, the surface of the cylinder equals the surface of the sphere; but the surface of the sphere equals four great circles; hence, the convex surface of the cylinder equals four great circles, and adding the two bases, we have the entire surface of the cylinder equal to six great circles; hence, the surface of the sphere is to the surface of the cylinder as 4 great circles is to 6 great circles, or as 4 to 6, or 2 to 3.

Second. The volume of the sphere is to the volume of the cylinder as 2 is to 3.

For, the volume of the sphere is $\frac{4}{3} \pi R^3$ (Th. X. C. I.), and the volume of the cylinder is $\pi R^2 \times CO$ (Th. II.), or $\pi R^2 \times 2R = \frac{6}{3} \pi R^3$; hence,

vol. S.: vol. cyl.:: $\frac{4}{3} \pi R^3$: $\frac{6}{3} \pi R^3$, or, :: 4 : 6, or 2 : 3,

Therefore, etc.

PRACTICAL EXAMPLES.

GEOMETRY.

 Required the convex surface and contents of a cylinder whose altitude is 16 inches, and diameter of the base 8 inches.

Ans. 402.12; 804.25.

2. Required the convex surface and volume of a cone whose altitude is 24 inches, and radius of the base 10 inches.

Ans. 816.816; 2513.28.

3. Required the convex surface of the frustum of a cone whose altitude is 36 inches, the radius of the upper base 6 inches, and lower base 21 inches.

Ans. 3308.1048.

4. Required the volume of a frustum of a cone whose altitude is 9 feet, diameter of lower base 4 feet, and of upper base 2 feet.

Ans. 65,9786

5. Required the surface and contents of a sphere whose diameter is 16 inches.

Ans. 804.2496; 2144.6656.

6. The surface of a sphere is 1809.5616 square inches; required its diameter and its volume.

Ans. D. = 24 inches.

7. The volume of a sphere is 113.0976 cubic inches; required its diameter and its surface.

Ans. D. = 6 inches.

8. Given the volume of a sphere 268.0832 cubic inches; required the altitude of the circumscribing cylinder.

Ans. 8 inches.

9. What is the surface of a zone of a single base whose altitude is 10 feet, the diameter of the sphere being 100 feet?

Ans. 3141.6 sq. ft.

10. Required the volume of a spherical segment of one base whose altitude is 2 feet, the diameter of the sphere being 8 feet.

Ans. 41.888 cubic feet.

11. Required the volume of a spherical segment whose greater diameter is 24 inches, less diameter 20 inches, and distance of bases 4 inches.

Ans. 1566.6112 cubic inches.

THEOREMS FOR ORIGINAL THOUGHT.

- 1. Prove that two great circles of a sphere bisect each other.
- 2. Prove that every great circle divides the sphere into two equal parts.

- Prove that the centres of a small circle and the sphere are in a fine perpendicular to the small circle.
- 4. Prove that the radius of a small circle is less than the radius of the sphere.
- Prove that circles whose planes are equidistant from the centre are equal.
- 6. Prove that the intersection of two spheres is a circle.
- 7. Prove that the arc of a great circle may be made to pass through any two points on the surface of a sphere.
- 8. Prove that if a cone and sphere be inscribed in a cylinder, that these bodies are to each other as 1, 2, and 3.

MISCELLANEOUS PROBLEMS .- PLANE FIGURES.

1. How many bricks 8 inches long and 4 inches wide will it take to pave a yard 20 feet by 16 feet?

Ans. 1440.

2. How much will it cost to plaster a room whose length is 24 ft., width 18 ft., and height 12 ft., at 16 ets. a square yard?

Ans. \$25.60.

3. What is the difference in area between a rectangle 60 feet by 40 feet, and a square which has the same perimeter?

Ans. 100 sq. ft.

4. What is the diagonal of a square whose area is equal to the area of a rectangle 16 inches by 25 inches?

Ans. 28.28 inches.

The diagonal of a square is \$\sqrt{50}\$ inches; required the side of the square.
 Ans. 5 inches.

6. Required the diagonal of a room whose length is 48 feet, width 20 feet, and height 39 feet.

Ans. 65 feet.

7. A yessel sailed north 20 miles, then west 30 miles, then north 60 miles, then west 70 miles; how far was it then from the point at which it started?

Ans. 128.06 miles.

8. The gable ends of a house are 48 ft. wide, and the ridge-pole is 10 ft. above the eaves; required the length of the rafters. Ans. 26 ft.

9. Required the area of an isosceles triangle whose base is 20 feet, and each of its equal sides 15 feet.

Ans. 111.803 square feet.

10. A flag-staff was broken, and fell, the broken part resting upon the upright, so that the end struck 48 feet from the foot; the upright part measured 86 feet; how long was the staff?

Ans. 96 feet.

11. I wish to enclose a square rod in the form of an equilateral triangle; what must be the length of each side?

12. Given the area of a circle 19,035 square inches; required the Ans. D. = 5 inches. diameter and circumference

13. The equal sides of an equilateral triangle are each 16 feet; what is the side of the inscribed square?

14. I have a plank 12 feet long which contains 15 square feet; what is the width of each end, if they are as 2 to 3? Ans. 12 in.; 18 in.

15. If the minute-hand of a clock is 6 inches long, over how much Ans. 75.398 square inches. space does it pass in 40 minutes?

16. What is the circumference of a circle whose diameter equals the diagonal of a square which contains 25 sq. rds.? Ans. 22,211112.

17. What is the diameter of a wheel which makes 200 revolutions in a minute, when the cars are going 30 miles an hour? Ans. $4\frac{1}{5}$ + feet.

18. A horse is fastened in a meadow, by a halter 20 feet long, to the top of a post 6 feet high; what is the area of the circle over which he Ans. 127.06 square yards. can graze?

19. Required the area of a circle in which the number expressing its area equals the number expressing its circumference.

Ans. 12,5664.

20. The area of a circular park is 4 acres; how long will it take to drive round it at the rate of 6 miles an hour? Ans. 2 min. 48 sec.

21. A circular garden containing 2 acres is bordered by a gravel walk of uniform width, which takes up 1 of its area; required the Ans. 22.308 feet. width of the walk.

22. If the hour-hand of a clock is 4 inches long, and the minutehand 6 inches, what is the difference of the surfaces over which they Ans. 108 91 square inches. travel in an hour?

MISCELLANEOUS PROBLEMS. - VOLUMES.

- 1. Required the surface of a brick 8 inches long, 4 inches wide, and Ans. 112 square inches.
- 2. Required the entire surface of a right pyramid whose base is a square 4 in. long, and the slant height 12 inches. Ans. 112 sq. in.
- 3. Required the entire surface of a cylinder whose altitude is 16 Ans. 829.3824 sq. in. in, the radius of the base being 6 inches.

4. Required the entire surface of a cone whose height is 16 feet, the radius of the base being 12 feet. Ans. 1206.3744 sq. ft.

5. Required the surface and contents of a sphere inscribed in a cube whose edge is 20 inches; and also the space between them.

6. The surface of a sphere is 6.305 square feet; required its diameter and volume. Ans. Vol. 1.48868 cubic feet.

*7. The volume of a sphere is 1.2411 cubic feet; required the diameter and surface. Ans. D. 16 inches.

8. The conyex surface of a cylinder whose altitude is 14 feet is 116.666square feet; required the diameter of its base. Ans. 2.65 ft.

9. What is the volume of a cylinder whose height is 20 feet, and the circumference of the base is 20 feet also? Ans. 636.64 feet.

10. The volume of a cylinder is 15.708 cubic feet; what is the altisude, if the diameter of the base is 2 feet? Ans. 5 feet.

11. The convex surface of a cone is 141.372 square feet, and the diameter of the base 4.5 feet; required the slant height and altitude.

Ans. 20 feet.

12. If a segment of 6 feet slant height be cut off of a cone whose slant height is 30 feet, the circumference of the base being 10 feet, what is the surface of the frustum? Ans. 144 square feet.

13. The convex surface of a frustum is 376,992 square feet, the slant height 20 feet, and the diameter of the less end 4 feet; what is the diameter of the greater end?

14. The volume of a cone is 8.83575 cubic feet, the altitude 15 feet; what is the diameter of the base? Ans. 18 inches.

15. The volume of a frustum of a cone is 65.9736 cubic feet, the diameter of one end is 4 feet and of the other 2 feet; required the altitude. Ans. 9 feet.

16. Required the entire surface of the frustum of a cone whose height is 12 feet, the radius of the lower base being 9 feet and the upper base 4 feet.

17. Required the entire surface of the frustum of a pyramid whose bases are squares, the lower 9 feet, the upper 4 feet, on a side, the altitude being 12 feet. Ans. 415.68 sq. ft.

18. How far must a person ascend above the earth that he may see one-third of the surface? Ans. 2 times the radius.

BOOK VIII.

SPHERICAL GEOMETRY.

1. SPHERICAL GEOMETRY has for its object the investigation of the properties and relations of those portions of the surface of a sphere which are bounded by arcs of great circles.

2. A SPHERICAL ANGLE is an angle included between the arcs of two great circles meeting at a point. The arcs are called sides, and the point at which they meet the vertex of the angle.

The measure of a spherical angle is the same as that of the diedral angle included between the planes of its sides. Spherical angles may be acute, right, or obtuse.

- 3. A SPHERICAL POLYGON is a portion of the surface of a sphere bounded by arcs of great circles. These arcs are called the sides of the polygon, and the points in which they meet the vertices. Each are is supposed to be less than a semicircumference.
- 4. A SPHERICAL TRIANGLE is a spherical polygon of three sides. Spherical triangles are classified in the same manuer as plane triangles.
- 5. A LUNE is a portion of the surface of a sphere bounded by two semi-circumferences of great circles.
- 6. A SPHERICAL WEDGE is a portion of a sphere bounded by a lune and the planes of its two sides.
- 7. A SPHERICAL PYRAMID is a portion of a sphere bounded by a spherical polygon and the circular sectors formed upon the sides of the polygon. The spherical polygon is called the base of the pyramid, and the centre of the sphere is called the vertex.

- 8. A POLE OF A CIRCLE is a point on the surface of the sphere equally distant from all points of the circumference of the circle.
- 9. A DIAGONAL of a spherical polygon is an arc of a great circle joining the vertices of any two angles not consecutive.
- 10. The SUPPLEMENT of an arc is what the arc lacks of being a semi-circumference.

THEOREM I.

Any side of a spherical triangle is less than the sum of the other two.

Let ABC be a spherical triangle, O being the centre of the sphere; then will any side, as AB, be less than the sum of the sides AC and BC.

For, draw the radii OA, OB, and OC, forming a triedral angle whose vertex is O; then the plane angle AOB is less than the sum of the angles AOC and BOC (B. V.

Th. XII.); hence the arc AB, which measures AOB (B. IV. Th. VIII.), is less than AC + BC, which measure AOC + BOC. Therefore, etc.

THEOREM II.

Any side of a spherical polygon is less than the sum of the other sides.

Let ABCDE be a spherical polygon; then will any side, as AE, be less than the sum of AB, BC, CD, and DE.

For, draw the diagonals BE and CE, dividing the polygon ABCDE into triangles. The arc AE is less than the sum of AB and EB, EB is less than the sum of BC and EC, and EC is less than the sum of ED and DC

(Th. I.); hence AE is less than the sum of AB, BC, CD, and DE.

Cor. The arc of a great circle measures the shortest distance between two points on the surface of a sphere.

For, if we divide any arc of a small circle joining the two points into equal parts, and through their extremities pass arcs of a great circle, the arc of the great circle joining the two given points will be less than the sum of these arcs (Th. II.). When the number of arcs becomes infinite, their sum is equal to the arc of the small circle. Therefore, etc.

THEOREM III.

The sum of the sides of a spherical polygon is less than the circumference of a great circle.

Let ABCDE be a spherical polygon, and O the centre of the sphere; then will the sum of its sides be less than the circumference of a great circle.

For, draw the radii OA, OB, OC, OD, and OE, forming a polyedral angle whose vertex is O; then the sum of the plane angles AOE, EOD, DOC, COB, and BOA is less than four right angles (B. V. Th. XIII.); hence the sum

of the arcs which measure them is less than the circumference of a great circle, which is the measure of four right angles. Therefore, etc.

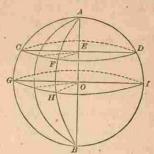

THEOREM IV.

If a diameter of a sphere be drawn perpendicular to the plane of any circle of the sphere, its extremities will be poles of that circle.

Let CFD be any circle of a sphere, and AB a diameter of the sphere perpendicular to the plane of CFD; then will A and B be the poles of the circle CFD.

The diameter AB, being perpendicular to the plane of CFD,

must pass through the centre E, since the diameter CD is a chord of the great circle ADBC, and must therefore be bisected by a liameter perpendicular to it (B, IV. Th. III.). If arcs of great circles AC, AF, and AD be drawn from A to different points of the circumference CFD, the chords of

those arcs will be equal (B. V. Th. III.); hence the arcs will be equal. But these arcs are the shortest lines that can be drawn from A to the points of the circumference (Th. II. Cor.); hence A, being equally distant from all points of the circumference, is a pole of the circle CFD (Def. 8). It may be proved in like manner that B is also a pole of the circle. Therefore, etc.

Cor. 1. The poles of a great circle are at equal distances from the circumference; and those of a small circle are at unequal distances, the sum of the distances being equal to the semi-circumference of a great circle.

For, let GHI be a great circle perpendicular to AB; then will the angles AOH, BOH, etc., be right angles, and the arcs AH, BH, etc., will be quadrants (B. V. Th. IX. C.). The arc AC is less than a quadrant, and BC is greater than a quadrant, and their sum equals ACB.

Cor. 2. If any point in the circumference of a great circle is joined with either pole by the arc of a great circle, the latter arc will be perpendicular to the circumference of the given circle.

For, the line AO being perpendicular to the plane GHI, any plane, as AOH, passed through it, will also be perpendicular to the plane GHI; hence the spherical angle AHG is a right angle, and the arc AH is perpendicular to the circle GHI.

Cor. 3. A point on the surface of a sphere at the distance of a quadrant from two points in the arc of a great circle, not at the extremities of a diameter, is a pole of the arc.

For, since the arcs AG and AH are quadrants, the angles AOG and AOH are right angles, and the line OA is perpendicular to the straight lines OG and OH; hence OA is a radius perpendicular to the plane GHI (B. V. Th. IV.), and the point A is therefore a pole of the arc HG.

Scholium. By means of poles we may with facility describe arcs of a circle on the surface of a sphere. For, revolving the arc AC around the pole A, the extremity C will describe the small circle CFD; and by revolving the quadrant AG around the pole, the extremity G will describe the great circle GHI.

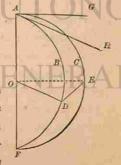

THEOREM V.

The angle formed by the intersection of two arcs of great circles is equal to the angle included between the tangents to these arcs at the point of intersection, and is measured by the arc of a great circle described from the vertex as a pole, and limited by the sides, produced if necessary.

Let the angle BAC be formed by the intersection of the two

arcs AB and AC; then it is equal to the angle HAG formed by the tangents AH and AG, and is measured by the arc ED of a great circle described from A as a pole.

For, the tangent AG, drawn in the plane of the arc AC, is perpendicular to the radius AO; and the tangent AH, drawn in the plane of the arc AB, is also perpendicular to the radius AO; hence the angle

HAG is equal to the angle formed by the planes ABDF and ACEF (B. V. Def. 6), which is the angle formed by the arcs AB and AC. Now, if the arcs AD and AE are both quadrants, the lines OD and OE are perpendicular to AO, and the angle DOE is equal to the angle of the planes ABDF and ACEF; hence the arc DE, which is the measure of DOE, is also the measure of BAC.

Cor. The opposite or vertical angles formed by two arcs of great circles intersecting each other are equal, and the sum of any two adjacent angles is equal to two right angles.

Scholium. The angles of spherical triangles are compared by means of the arcs of great circles described from their vertices as poles and included between their sides. Thus a spherical angle can always be constructed equal to a given angle.

THEOREM VI.

If from the vertices of the angles of a spherical triangle, as poles, ares be described forming a spherical triangle, the vertices of the angles of the second triangle will be respectively poles of the sides of the first.

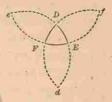

From the vertices A, B, C as poles describe the arcs DE, EF, FD, forming the triangle EFD; then will the vertices D, E, F be respectively poles of the sides BC, AC, AB.

For, since the point A is the pole of the arc EF, the distance AE is a quadrant; and since the point C is the pole of the arc

DE, the distance CE is a quadrant; hence the point E is at a quadrant's distance from A and C, and therefore it is the pole of the arc AC (Th. IV. Cor. 3). In the same manner it may be shown that D is the pole of CB, and F the pole of AB. Therefore, etc.

Scholium. The triangle ABC may be described when DEF is given, as DEF is described when ABC is given. Triangles thus related are called polar triangles or supplemental triangles.

Since great circles intersect each other in two points, three other triangles may be formed by producing the arcs DE, FE and FD; but the central triangle only is taken as a polar triangle, being the only one in which the vertices A and D are on

the same side of BC, the vertices B and E on the same side of AC, and the vertices C and F on the same side of AB.

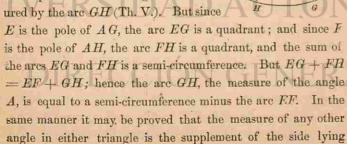

THEOREM VII.

In two polar triangles, any angle of one triangle is measured by the supplement of the side lying opposite to it in the other.

Let ABC and DEF be two polar triangles; then will any angle of either triangle be measured by the supplement of the side lying opposite

For, produce AB and AC, if necessary, till they meet EF in H and G. Since A is the pole of EF, the angle A is measured by the arc GH (Th. V.). But since

opposite to it in the other.

THEOREM VIII.

The sum of the angles of a spherical triangle is less than six right angles and greater than two.

For, any angle, being measured by the supplement of the side lying opposite to it in the polar triangle (Th. VII.), is less than two right angles; hence the sum of the three angles is less than six right angles. Also, the measure of the sum of the three angles is equal to three semi-circumferences minus the three sides of the polar triangle. But the three sides of a triangle are less than a circumference (Th. III.); hence the measure of the sum of the three angles is greater than a semi-circumference, and the sum of the angles is greater than two right angles. Therefore, etc.

Cor. 1. A spherical triangle may have two, or even three, right angles; also two, or even three, obtuse angles.

Cor. 2. If the triangle ABC has two right angles, it is called bi-rectangular. Since the arcs AB and AC are perpendicular to BC, they must both pass through the pole of BC; hence their point of intersection, A, is the pole, and the arcs AB and AC are quadrants.

If the angle A is also a right angle, the triangle is tri-rectangular, the sides being quadrants. Four tri-rectangular triangles make up the surface of a hemisphere, and eight that of a sphere.

Scholium. The sum of the three angles of a spherical triangle is not constant, like that of the angles of a plane triangle, but varies between two right angles and six without ever reaching either limit. Two angles, therefore, being given, do not serve to determine the third. The excess of the sum of the angles over two right angles is called the spherical excess, and taking

the right angle as the unit may be represented thus: A + B + C - 2 = spherical excess.

THEOREM IX.

Two spherical triangles on the same sphere or on equal spheres

- 1. When two sides and the included angle of the one are equal to two sides and the included angle of the other.
- 2. When two angles and the included side of the one are equal to two angles and the included side of the other.
 - 3. When the three sides are respectively equal.

The three cases of this theorem may be demonstrated, as in plane triangles, by applying one of the given triangles to the other or to its symmetrical triangle.

Scholium. The symmetrical triangle is formed thus:

Let AB, BC and AC be three arcs of great circles, from which either of the two triangles ABC, ABC' may be formed. These two triangles, although all their parts are equal, are not capable of superposition, because in inverting one in order to bring the corresponding parts together the convex surfaces would be turned toward each other. Such triangles are called symmetrical triangles.

Cor. The circles passed through the vertices of two mutually equilateral triangles on the same sphere or on equal spheres are equal.

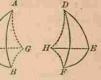

For, the plane triangles formed by the chords of the sides of these spherical triangles must be equal; hence, if the spherical triangles are applied to each other, the vertices of the spherical triangles will coincide, and the circles passing through the vertices are equal.

THEOREM X.

Two symmetrical spherical triangles are equal in area.

Let ABC and DEF be two symmetrical triangles, in which AB equals DF, AC equals DE, and CB aquals EF. Then will the area of the two triangles be equal.

For, let G be the pole of the small circle passing through the points A, B,

and C, and H the pole of the circle passing through D, E, and F; these circles will be equal (Th. IX., C.). Join A, B, and C with G, and D, E, and F with H, by arcs of great circles; these arcs will all be equal, since they measure the distances from the circumferences of equal circles to their poles. The triangles ACG and DEH, being isosceles and having equal sides, may be applied to each other, and are equal in area; so also CBG is equal to EFH, and ABG to DFH. Hence ACG + CBG - ABG = DEH + EFH - DFH, or, reducing, ABC = DEF. Therefore, etc.

Scholium. If the point G fall within the triangle ACB the point H will also fall within the triangle DEF, and the areas of the triangles will equal the sum of the three isosceles triangles.

THEOREM XI.

If two triangles on the same, or on equal spheres, are mutually equiangular, they are also mutually equilateral.

Since the two given triangles are mutually equiangular, their polar triangles must be mutually equilateral (Th. VII.), and consequently mutually equiangular (Th. IX.). But if these polar triangles are mutually equiangular, the given triangles are mutually equilateral (Th. VII.).

Scholium. This proposition does not extend to plane triangles, for similar plane triangles are not necessarily mutually equilateral. But two spherical triangles on the same or equal spheres cannot be similar without being equal.

THEOREM XII.

The surface of a lune is to the surface of a sphere as the angle of the lune to four right angles, or as the are which measures that angle is to the circumference of a great circle.

Let ABCDA be a lune on the surface of a sphere, and BD the arc of a great circle whose poles are A and C, the vertices of the angles of the lune; then will the surface of the sphere as the arc RD to the circumference BDEG.

For, if we divide the arc BD and the circumference BDEG into equal

parts, BF being one of those parts, and pass planes through the diameter AC and each of the points of division, the surface of the sphere will evidently be divided into equal lunes, of which the given lune will contain as many as there are parts in the arc BD; hence, the lune ABCDA is to the whole surface of the sphere as the arc BD is to the circumference BDEG; and the same may also be shown when the arc BD and the circumference are incommensurable. But BD is the measure of the angle of the lune, and the circumference is the measure of four right angles. Therefore, etc.

Cor. 1. Lunes on the same sphere or on equal spheres are to each other as their angles.

Cor. 2. Taking the right angle as the unit of angles, and

denoting the angle of a lune by A, the area by L, and the surface of a tri-rectangular triangle by T, we have

L:8T::A:4:

whence.

$$L = T \times 2A$$
.

Therefore the area of a lune is equal to the tri-rectangular triangle multiplied by twice the angle of the lune.

Cor. 3. A spherical wedge bears the same relation to the entire sphere as the angle of the wedge to four right angles, as may be shown by a similar course of reasoning to that employed in the theorem; hence the volume of the wedge is equal to the lune which forms its base, multiplied by one-third of the radius.

THEOREM XIII.

If two circumferences of great circles intersect on the surface of a hemisphere, the sum of either two of the opposite triangles thus formed is equal to a lune whose angle is equal to that formed by the circles.

Let the circumferences AEBF, CEDF intersect on the surface of a hemisphere; then will the sum of the opposite triangles AEC, DEB be equal to the lune whose angle is AEC.

For, since AEB and EBF are semicircumferences, if we take away the common part EB we have AE equal to BF. In the same way, we find

CE equal to DF and BD equal to AC; hence the two triangles AEC and BFD, having their sides equal, must be symmetrical, and therefore equal in area (Th. X.). But the sum of the triangles DEB and BFD is equal to the lune EDFBE, whose

BOOK VIII.

173

angle is AEC; hence the sum of AEC and DEB equals the lune whose angle is AEC. Therefore, etc.

Scholium. It is evident that the two spherical pyramids which have the triangles ACE and BED for bases are together equal to the spherical wedge whose angle is AEC.

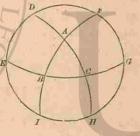

THEOREM XIV.

The area of a spherical triangle is equal to its spherical excess multiplied by the tri-rectangular triangle.

Let ABC be a spherical triangle; then, representing the

tri-rectangular triangle by T, the surface of the given triangle will be equal to $(A + B + C - 2) \times T$.

For, produce the sides until they meet the circumference of a great sircle, drawn without the triangle, forming three sets of opposite triangles. By the last theorem the area

of each of these sets is equal to the lune whose angle is the corresponding angle of the triangle. Hence (Th. XII., Cor. 2),

$$ADF + AHI = 2 A \times T$$
.

$$BEI + BFG = 2 B \times T$$
.

$$CGH + CDE = 2 C \times T.$$

But the sum of these six triangles exceeds the hemisphere, or 4 T, by twice the triangle ABC; hence, by adding the equations and substituting in the first member its value, we have

$$4T+2ABC=2A\times T+2B\times T+2C\times T;$$

reducing,
$$ABC = (A + B + C - 2) \times T$$
.

But A+B+C-2 is the spherical excess of the triangle (Th. VIII. Sch.), and T is the tri-rectangular triangle. Therefore, etc.

THEOREM XV.

The area of a spherical polygon is equal to its spherical excess multiplied by the tri-rectangular triangle.

Let ABCDE be a spherical polygon. If we draw the diag-

onals AC and AD, the polygon will be divided into as many triangles as there are sides, less two. Now, the area of each triangle is equal to the sum of its angles minus two right angles, multiplied by the tri-rectangular triangle; and the area of the polygon, or the

sum of all the triangles, is equal to the sum of all the angles of the triangles, or the sum of the angles of the polygon, diminished by two right angles, taken as many times as the polygon has sides, less two, and the difference multiplied by the trirectangular triangle; which is the spherical excess of the polygon multiplied by the trirectangular triangle. Therefore, etc.

Cor. If we represent the sum of the angles by S, and the number of the sides by n, we shall have

the area of a polygon = $[S-2\ (n-2)] \times T$; and reducing have area of a polygon = $(S-2\ n+4) \times T$.

PRACTICAL EXAMPLES

- 1. Find the area of a spherical triangle each of whose angles is 70°.
- 2. Find the area of a spherical polygon of six sides each of whose angles is 150° .

 Ans. π R²
- Given the spherical triangle whose angles are respectively 80°, 90°, and 140°, to find the sides of its polar triangle.

Ans. 100°; 90°; 40°.

4. If the sides of a triangle are respectively 75°, 110°, and 130°, what are the angles of its polar triangle? Ans. 105°; 70°; 50°.

5. What is the area of a bi-rectangular triangle whose vertical angle is 108°?
Ans. ³/₂ π R².

6. Find the area of a spherical triangle whose angles are 60°, 90°, and 120°, the diameter of the sphere being 8. Ans. 8 π .

7. Find the area of a lune, its angle being 45°. Ans. $\frac{1}{2}$ π R².

8. Find the area of a lune, the angle being 54° and radius of the phere being 5.

Ans. 15 π .

9. Find the volume of a spherical wedge, the angle of the lune being

Ans. $\frac{4}{15} \pi R^3$.

10. Find the volume of a spherical wedge, the angle of the lune being 36° and the diameter of the sphere 10. Ans. $16^2_3 \pi$.

11. Find the angles of an equilateral spherical triangle whose area is equal to the surface of a great circle.

Ans. 120°.

12. What must be the angles of an equilateral spherical triangle that its area may be equal to an equilateral spherical hexagon, each of whose angles is 130°?

Ans. 80°.

THEOREMS FOR ORIGINAL THOUGHT.

1. Prove that in an isosceles spherical triangle the angles opposite the equal sides are equal.

2. Prove that a spherical triangle having two equal angles is isosceles.

3. In any spherical triangle the greater side is opposite the greater angle, and conversely.

4. If from any point of a hemisphere two arcs of great circles are drawn perpendicular to its circumference, the shorter of the two arcs is the shortest arc that can be drawn from the given point to the circumference.

5. Two oblique arcs drawn from the same point to points of the circumference at equal distances from the foot of the perpendicular are equal.

6. Of two oblique arcs, that which meets the circumference at the greatest distance from the foot of the perpendicular is the longer.

7. Prove that the area of a spherical triangle, each of whose angles is 4 of a right angle, is equal to the surface of a great circle.

MENSURATION.

MENSURATION OF LENGTHS AND SURFACES.

1. MENSURATION is the science which treats of the measurement of geometrical magnitudes.

2. The AREA of a figure is its quantity of surface; it is expressed by the number of times which it contains the unit of measure.

3. This *Unit of Measure* is a square whose side is some known length; as, an inch, a foot, etc.

4. The unit of surface has generally the same name as the linear unit; thus, if the linear unit is one foot, the surface unit is one square foot, etc.

5. Some superficial units have no corresponding linear unit of the same name; as, the rood and acre.

6. To refresh the memory, we give a few of the more important measures of surfaces.

1 rood = 40 perches, or square rods.

1 acre = 4 roods.

1 square mile = 640 acres.

Also.

1 chain = 100 links = 4 rods.

10 chains = 1 furlong.

1 square chain = $100 \times 100 = 10{,}000$ square links.

1 acre = 10 square chains = 100,000 square links.

5. What is the area of a bi-rectangular triangle whose vertical angle is 108°?
Ans. ³/₂ π R².

6. Find the area of a spherical triangle whose angles are 60°, 90°, and 120°, the diameter of the sphere being 8. Ans. 8 π .

7. Find the area of a lune, its angle being 45°. Ans. $\frac{1}{2}$ π R².

8. Find the area of a lune, the angle being 54° and radius of the phere being 5.

Ans. 15 π .

9. Find the volume of a spherical wedge, the angle of the lune being

Ans. $\frac{4}{15} \pi R^3$.

10. Find the volume of a spherical wedge, the angle of the lune being 36° and the diameter of the sphere 10. Ans. $16^2_3 \pi$.

11. Find the angles of an equilateral spherical triangle whose area is equal to the surface of a great circle.

Ans. 120°.

12. What must be the angles of an equilateral spherical triangle that its area may be equal to an equilateral spherical hexagon, each of whose angles is 130°?

Ans. 80°.

THEOREMS FOR ORIGINAL THOUGHT.

1. Prove that in an isosceles spherical triangle the angles opposite the equal sides are equal.

2. Prove that a spherical triangle having two equal angles is isosceles.

3. In any spherical triangle the greater side is opposite the greater angle, and conversely.

4. If from any point of a hemisphere two arcs of great circles are drawn perpendicular to its circumference, the shorter of the two arcs is the shortest arc that can be drawn from the given point to the circumference.

5. Two oblique arcs drawn from the same point to points of the circumference at equal distances from the foot of the perpendicular are equal.

6. Of two oblique arcs, that which meets the circumference at the greatest distance from the foot of the perpendicular is the longer.

7. Prove that the area of a spherical triangle, each of whose angles is 4 of a right angle, is equal to the surface of a great circle.

MENSURATION.

MENSURATION OF LENGTHS AND SURFACES.

1. MENSURATION is the science which treats of the measurement of geometrical magnitudes.

2. The AREA of a figure is its quantity of surface; it is expressed by the number of times which it contains the unit of measure.

3. This *Unit of Measure* is a square whose side is some known length; as, an inch, a foot, etc.

4. The unit of surface has generally the same name as the linear unit; thus, if the linear unit is one foot, the surface unit is one square foot, etc.

5. Some superficial units have no corresponding linear unit of the same name; as, the rood and acre.

6. To refresh the memory, we give a few of the more important measures of surfaces.

1 rood = 40 perches, or square rods.

1 acre = 4 roods.

1 square mile = 640 acres.

Also.

1 chain = 100 links = 4 rods.

10 chains = 1 furlong.

1 square chain = $100 \times 100 = 10{,}000$ square links.

1 acre = 10 square chains = 100,000 square links.

THE TRIANGLE.

7. The AREA is found by the following rules:

RULE 1.—Multiply the base by one-half of the altitude; or, RULE 2.—Take half the sum of the sides, subtract from it each side separately, multiply the half sum and these remainders together, and take the square root of the product.

1. What is the area of a triangular field whose base is 40 rods and altitude 16 rods?

Ans. 2 acres.

2. Required the area of a triangle whose sides are 20, 30, and 40 chains respectively.

Ans. 29 A. 8 P.

3. A man has a triangular garden whose sides are 150, 200, and 250 feet respectively; required the area.

Ans. 1666.66 yards.

THE QUADRILATERAL.

8. Parallelogram.—The area is found as follows: Rule.—Multiply the base by the altitude.

1. What is the area of a parallelogram 9 feet long and 7 feet wide?

Ans. 63 square feet.

2. How many acres in a square field whose side is $70\frac{1}{2}$ chains?

Ans. 497 A. 4 P.

3. A man has a lot in the form of a rhombus, whose length is 333 feet and altitude 33.35 feet; required its area.

Ans. 1233.95 square yards.

9. TRAPEZOID.—The AREA is found as follows:
RULE.—Multiply one-half of the sum of the parallel sides
by the altitude.

1. Required the area of a trapezoid, one side being 192 inches and the other 96 inches, and altitude 12 feet.

Ans. 144 square feet.

2. What is the area of a plank 24 feet long, 18 inches wide at one end and 12 inches at the other?

Ans. 30 square feet.

3. A farmer has a field in the form of a trapezoid, whose parallel sides are 95 and 75 rods respectively, and the perpendicular distance between them 65 rods; how much land in the field?

Ans. 34 A. 2 R. 5 P.

10. TRAPEZIUM.—The AREA is found as follows:

Rule.—Divide the trapezium into two triangles by a diagonal, find the area of each triangle, and take their sum.

1. What is the area of a trapezium whose diagonal is 290 inches, and the altitudes of the triangles, the diagonal being the base, are 60 and 80 inches respectively?

Ans. 140 square feet, 140 square inches.

2. Required the area of a trapezium the lengths of whose sides are respectively 40, 60, 50, and 70 chains, and the diagonal 80 chains.

Ans. 289 A. 1 R. 24 P.

POLYGONS OF ANY NUMBER OF SIDES.

11. Regular Polygons.—The area is found as follows: Rule.—Multiply half the perimeter by the perpendicular let fall from the centre on one of the sides.

1. What is the area of a regular hexagon whose side is 14.6 feet and perpendicular 12.64 feet?

Ans. 61.5147 square yards.

2. Required the area of an octagon whose sides are 9.941 feet and its perpendicular 12 feet.

Ans. 477.168 square feet.

12. The following table shows the areas of ten regular polygons when the side is 1:—

0.4	330127 Octagon	4.8284271
Triangle 0.4	000000 Nonagon	6.1818242
Square		7.6942088
Pentagon 1.7	080762 Undecagon	9.3656404
Hexagon 2.5		11.1961524
Heptagon	1999174 DoucenBan	

Now, since the areas of similar polygons are to each other as the squares of their homologous sides, to find the area of a regular polygon we have the following

RULE.—Square the side of the polygon, and multiply by the tabular area set opposite the polygon.

3. What is the area of a regular hexagon whose side is 5 inches long?

Ans. 64.9519 square inches.

4. Required the area of an octagon whose sides are each
3 feet 4 inches.

Ans. 53.649 square feet.

13. IRREGULAR POLYGON.—The AREA is found as follows: Rule.—Draw diagonals dividing the polygon into triangles, find the area of these triangles, and take the sum.

1. In the irregular pentagon ABCDE, the diagonal AC is 24 inches, the diagonal AD is 18 inches, the altitude of the triangle ABC is 8 inches, of ACD is 10 inches, and of AED 6 inches; required the area.

Ans. 240 square feet.

2. In the irregular hexagon ABCDEF, the side AB is 268, BC 249, CD 310, DE 290, EF 199, and AF 246 links, and the diagonals AC 459, CE 524, and AE 326 links; required the area. Ans. 1 A. 2 R. 22 P. 13 yd. 47 ft.

THE CIRCLE.

14. The CIRCUMFERENCE is found by the following Rule.—Multiply the diameter by 3.1416.

Note.—Hence, the diameter equals the circumference divided by 8.1416, or multiplied by .31831.

- 1. What is the circumference of a circle whose diameter is 50 inches?

 Ans. 157.08 inches
- 2. A man has a circular fish-pond 32 rods in diameter; what is the distance around it?

 Ans. 100.5312 rods.
- 3. Required the diameter of a water-wheel whose circumference is 78.54 feet.

 Ans. 25 feet.
- 4. A man has a garden in the form of a circle, the diameter being 45 rods; what is the distance around it?

 Ans. 141.372 rods.
- 15. The LENGTH OF AN ARC, when its degrees and radius are given, is found as follows:

Rule.—Multiply the number of degrees by the decimal .01745, and the product by the radius.

- 1. The degrees in an arc are 45, and the radius 10; what is the length of the arc?

 Ans. 7.852.
- 2. What is the length of an arc of 32° 38′ 42″, the radius being 25 inches?

 Ans. 14.2414 inches.

16. When the chord and chord of the half are are given. Rule.—From 8 times the chord of half the arc, subtract the shord of the whole arc, and divide the remainder by 3.

1. The chord of an arc is 96 inches, and the chord of half the arc is 60 inches; what is the length of the arc?

Ans. 128 inches,

2. The chord of an arc is 16 inches, and the diameter of the circle is 20 inches; what is the length of the arc?

Ans. 18.5178 inches.

17. The AREA OF A CIRCLE is found as follows:

RULE I.—Multiply the circumference by one-fourth of the diameter, or the square of the radius by 3.1416.

Rule II.—Multiply the square of the diameter by .7854, or the square of the circumference by .07958.

(Let the pupil prove the last rule from the previous principles.)

1. What is the area of a circle whose diameter is 50 inches and circumference 157.08 inches?

Ans. $1963\frac{1}{2}$ square inches.

2. Required the area of a circle whose diameter is 18 Ans. 254.4696 square inches. inches.

3. What is the area of a circular garden whose circum Ans. 644.598 square rods. ference is 90 rods?

18. The AREA OF A SECTOR is found as follows:

RULE .- I. Multiply the arc by one-half the radius; or,

II. The sector is to the circle as the number of degrees in the sector is to 360°.

1. What is the area of a circular soctor whose are contains 18°, the diameter of the circle being 6 feet?

Ans. 1.4137 square feet.

2. Required the area of a sector, the chord of half the are being 30 inches, and the radius 50 inches.

Ans. 1523.45 square inches.

19. The AREA OF A SEGMENT is found as follows:

RULE. Find the area of the sector having the same arc, and also the area of the triangle formed by the chord of the segment and the radii of the sector.

If the segment is greater than a semicircle, add the two areas; if less, subtract them.

1. Required the area of a segment whose height is 2 inches, and chord 20 inches. Ans. 26.864 square inches.

2. What is the area of a segment whose height is 18 inches the diameter of the circle being 50 inches?

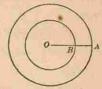

Ans. 632 sq. in.

3. Required the area of a segment whose arc is 180°, and Ans. 226.1952 radius of circle 12 feet.

20. The AREA OF A CIRCULAR RING is found as follows:

RULE .- Find the difference of the squares of the radii, and multiply it by 3.1416.

DEMONSTRATION .- Let the figure represent two circles having a common centre O; then the difference between them will be a circular ring. The area of circle OA is πOA^2 , and of OB is πOB^2 ; the difference is $\pi OA^2 - \pi OB^2 = \pi (OA^2 - OB^2)$, which proves the rule.

1. What is the area of the circular ring when the diameters are 20 and 30?

Ans. 392.70.

2. A circular park 400 feet in diameter has a carriageway around it 24 feet wide; required the area of the carriage-way. Ans. 3149.9776 square yards.

21. The SIDE OF AN INSCRIBED SQUARE is found thus: Rule.—Multiply the diameter by .7071, or multiply the circumference by .2251.

1. What is the side of a square that can be cut out of a circular board whose diameter is 14 inches?

Ans. 9.899 inches.

2. How large a square can be cut out of a circular board whose circumference is 400 inches?

Ans. 90.04 inches.

THE ELLIPSE.

22. An ELLIPSE is a plane figure bounded by a curve. the sum of the distances from every point of which to two fixed points is equal to the line drawn through those points and terminated by the curve.

The two points are called foci; the line through the foci is the transverse axis; a line perpendicular to this through the centre is the conjugate axis.

23. The area is found by the following

RULE.—Multiply half of the two axes A together, and multiply that product by 3.1416.

1. What is the area of an ellipse whose transverse axis is 20 inches and conjugate axis 16 inches?

Ans. 251.328.

2. Required the area of an elliptical mirror whose length is 6 feet and breadth 5 feet.

Ans. 23.562 square feet.

MENSURATION OF VOLUMES.

24. Mensuration of Volumes is the process of determining their surface and contents.

25. The Contents of a volume is the number of times it contains a given unit of measure.

26. The Unit of Measure of a volume is a small cube whose dimensions are known.

MEASURES OF VOLUMES.

1 cubic foot == 1728 cubic inches.

" yard = 27 " feet

" rod = $4492\frac{1}{8}$ " feet.

1 wine gallon = 231 " inches.

1 ale gallon = 282 " inches.

1 bushel = 2150.42 " inches.

1 cord = 128 " feet.

THE PRISM.

27. The convex surface of a right prism is found thus: Rule.—Multiply the perimeter of the base by the altitude. To find the entire surface, we add the bases.

1. What is the convex surface of a triangular prism, the three sides of whose base are respectively 6, 7, and 8 inches, and the height 50 inches?

Ans. 1050 square inches.

2. What is the entire surface of a cube, the length of each side being 16 inches?

Ans. $10\frac{2}{3}$ square feet.

3. What is the entire surface of the triangular prism given in the first problem? Ans. 1090.66 square inches.

28. The contents of a prism are found thus:

Rule.—Multiply the area of the base by the altitude of the prism.

1. Required the contents of a cube whose sides are 30 inches.

Ans. 15.625 cubic feet.

2. Required the contents of a square prism whose altitude is 27 feet, and the side of the base 4 feet?

Ans. 432 cubic feet.

3. Required the contents of a triangular prism whose altitude is 24 feet, the sides of the base being 3, 4, and 5 feet respectively.

Ans. 144 cubic feet.

THE PYRAMID.

29. The CONVEX SURFACE OF A RIGHT PYRAMID is found thus:

Rule.—Multiply the perimeter of the base by one-half the slant height.

 What is the convex surface of a triangular pyramid whose sides are 3, 4, and 5 feet, and slant height 20 feet?
 Ans. 120 square feet. 2. Required the convex surface of a pentangular pyramid whose sides are each 5 feet, and slant height 60 feet.

Ans. 750 square feet.

30. The contents of a pyramid are found thus:

RULE. Multiply the base by one-third of the altitude.

- 1. Required the contents of a pyramid whose base is a hexagon, each side being 5 feet, and whose altitude is 20 feet.

 Ans. 433.013.
- 2. The pyramid of Cheops is 480 feet high, and the base is a square 763.4 feet on a side; required its solid contents.

 Ans. $93244729\frac{3}{8}$ cubic feet.

THE CYLINDER.

31. The CONVEX SURFACE and CONTENTS are found thus:
RULE 1.—The surface equals the circumference of the base
multiplied by the altitude.

Rule 2.—The contents equal the area of the base multiplied by the altitude.

- 1. What is the convex surface of a cylinder 12 feet long and 6 feet in diameter?

 Ans. 226.1952 square feet.
- 2. Required the convex surface of a cylinder whose length is 20 feet and the diameter of the base 8 feet.

Ans. 502.656 square feet.

- 3. A man has a log 12 feet long and about 62 feet in diameter; required its contents. Ans. 418.88 cubic feet.
- 4. The Winchester bushel is a cylinder containing 2150.42 cubic inches, its height being 8 inches; what is its diameter?

 Ans. $18\frac{1}{2}$ inches.

THE CONE.

32. The CONVEX SURFACE and CONTENTS are found thus:
RULE 1.—The surface equals the circumference of the base
into one-half of the slant height.

Rule 2.—The contents equal the area of the base into one third of the altitude.

1. Find the convex surface and contents of a cone, the diameter of the base being 6 ft. and altitude 4 ft.

Ans. Sur. = 47.124.

2. Find the surface and contents of a cone whose slant neight is 26 in. and radius of the base 10 in.

Ans. Vol. = 2513.28.

THE FRUSTUM OF A PYRAMID AND CONE.

33. The convex surface is found by the following Rule.—Find the sum of the perimeters or circumferences of the two bases, and multiply it by one-half of the slant height.

1. Required the convex surface of the frustum of a square pyramid whose slant height is 24 ft., the side of the lower base 12 ft., and of the upper base 8 ft.

Ans. 960 sq. ft.

2. Required the surface of a frustum of a cone whose slant height is 20 ft., the diameter of the lower base being 12 ft., and of the upper base 8 ft.

Ans. 628.32 sq. ft.

34. The contents of a frustum are found as follows:

Rule.—Find the sum of the two bases and the square root of their product, and multiply this sum by one-third of the altitude of the frustum.

Note.—In a frustum of a cone the following formula gives a shorter rule:— $V = \frac{\pi}{3} (R^2 + r^2 + R \cdot r) \times h$.

- 1. What is the amount of timber in a log which measures 40 feet in length, the radius of one base being 6 feet and of the other 3 feet?

 Ans. 2638.944 cubic feet.
- 2. Required the contents of the frustum of a regular hexagonal pyramid, the side of the greater end being 3 feet, that of the less 2 feet, the height being 24 feet.

Ans. 394.9075 cubic feet.

3. A cask, consisting of two equal conic frustums joined at their larger ends, has its bung diameter 30 inches, and its head diameter 20 inches; how many gallous of wine will it hold if 3½ feet long?

Ans. 90.44 gallons.

THE SPHERE.

35. The SURFACE OF A SPHERE is found as follows:

Rule.—Multiply the diameter by the circumference; or,

Square the radius, and multiply it by 4 and 3.1416.

1. Required the surface of a sphere whose diameter is
Ans. 6.305 square feet.

2. How many square miles on the surface of the earth, the diameter being about 7912 miles?

Ans. 196,663,355 square miles.

36. The SURFACE OF A ZONE is found as follows:

RULE.—Multiply the height of a zone by the circumference of a great circle of the sphere.

1. The diameter of a sphere is 25 feet, and the height of the zone 6 feet; what is the surface of the zone?

Ans. 471.24 square feet.

2. Required the surface of the torrid zone, the diameter of the earth being 7912 miles.

. Ans. 78,419,272 square miles.

Note.—This is to be solved after the pupil has completed Trigonometry.

37. The contents of a sphere are found as follows: Rule.—Multiply the surface by one-third of the radius; or, Multiply the cube of the diameter by \(\frac{1}{6} \) of 3.1416.

1. Required the contents of a sphere whose diameter is 17 inches.

Ans. 2572.4468 cubic inches.

 Required the contents of the planet Mars, the diameter being about 4500 miles.

Ans. 47713050000. 38. The contents of a spherical segment of one base are found thus:

Rule.—Add the square of the height to three times the square of the radius of the base; multiply this sum by the height, and the product by .5236; or, see Th. X. B. VII.

Note.—For the volume of a segment of two bases, see B. VII. Th. X. C. 4.

1. Required the contents of the segment of a sphere whose height is 4 inches, and radius of the base 8 inches.

Ans. 435.635 cubic inches.

2. Find the volume of either temperate zone, the diameter of the earth being 7912 miles.

Ans. 54,919,403,678 cubic miles.

Note.—The pupil will solve this after completing Trigonometry.

CYLINDRICAL RINGS.

39. A CYLINDRICAL RING is formed by bending a cylinder until the two ends meet. We find its surface by the following

Rule.—To the thickness of the ring add the inner diameter; multiply this sum by the thickness of the ring, and the product by 9.8696.

Note.—For contents, multiply the sum by the square of $\frac{1}{2}$ the thickness, instead of the thickness, the other part of the rule being the same as for surface.

1. The thickness of a cylindrical ring is 4 inches, and the inner diameter 18 inches; what is the convex surface?

Ans. 868.52 square inches.

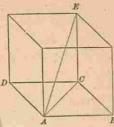

2. The thickness of a cylindrical ring is 2 inches, and the inner diameter 1 foot; required its contents.

Ans. 138:1744 cubic inches.

40. The SIDE OF AN INSCRIBED CUBE is found thus:

Rule.-Multiply the diameter by .57736, or the radius by 1.15472.

DEMONSTRATION. - Let the cube in the margin represent an inscribed cube; then will AE be the diameter of the sphere. Let the diameter be denoted by D, and the radius by R. Now, $\overline{AE^2}$ or $D^2 = AC^2 + \overline{CE^2}$; but D $AC^{2} = AB^{2} + \overline{BC^{2}}$; hence, $D^{2} = AB^{2} +$ $BC^2 + CE^2$, or, since the sides are equal, $D^2 = 3 AB^2$, or, $D = AB \times \sqrt{3} = AB \times$ 1.73205, and, consequently, $AB = D \times_{\text{T.73205}} = D \times .57736$, or AB =

 $R \times 1.15472$

1. Required the side of a cube that can be cut out of a sphere whose diameter is 16 inches. Ans. 9.23776.

2. Required the volume of a cube inscribed in a sphere whose circumference is 18.849552 inches.

Ans. 41.571219 cubic inches.

41. The VOLUME OF AN IRREGULAR BODY is found thus: Rule.-Immerse the body in a vessel of known dimensions, containing water; note the rise in the water, and calculate

accordingly.

1. A stone immersed in a cylindrical vessel 10 inches in diameter, raised the water 5 inches; required the volume of the stone. Ans. 392.70. cubic inches.

2. A man put a stone into a vessel 14 cubic feet in capacity, and it then required 21 quarts of water to fill the vessel; required the volume of the stone.

Ans. 13.9164 cubic feet.

MISCELLANEOUS PROBLEMS-PLANE FIGURES.

- 1. How many yards of paper that is 30 inches wide will it require to cover the wall of a room $15\frac{1}{4}$ feet long, $11\frac{1}{4}$ feet wide, and $7\frac{3}{4}$ feet high? Ans. 55.2833 yards.
- 2. A ladder 130 feet long, with its foot in the street, will reach on one side to a window 78 feet high, and on the other to a window 50 feet high; what was the width of the street? Ans. 224 feet.
- 3. The diameter of a circle is 4 feet; required the area of the inscribed Ans. 3 /3 square feet.
- 4. From a plank 16 inches broad, 6 square ft. are to be sawed off; at what distance from the end must the line be struck? Ans. 41 feet.
- 5. The ball on the top of a church is 6 feet in diameter; what did the gilding of it cost, at 8 cents per square inch? Ans. \$1302.884.
- 6. The area of an equilateral triangle, whose base falls on the diameter and its vertex in the middle of the arc of a semicircle, is 100 square feet; what is the diameter of the semicircle? Ans. 26.32148.
- 7. The cost of paving a semicircular plot of ground, at 20 cents a square foot, amounted to \$20; required its diameter. Ans. 15.9576.
- 8. A gentleman has a garden 80 feet long and 60 feet wide; what must be the width of a walk extending around the garden, which shall occupy one-half of the ground?
- 9. Required the perimeter of a regular dodecagon which shall con tain the same area as a circle whose circumference is 1000 feet.

Ans. 1011.67 feet.

- 10. If a horse tied to a post in the centre of a field by a rope I chain 78 links can graze upon an acre, what length of rope would allow it to graze upon 54 acres? Ans. 4 chains 154 links.
- 11. A has a circular garden which is 20 rods, and B has a circular garden whose area is 61 times as great; what is the diameter of B's garden? Ans. 50 rods.
- 12. A has a circular garden, and B a square one; the distance around each is 64 rods; which contains the most land, and how much?

Ans. 69,948 square rods.

13. Atherton has a circular garden and Fell has a square one, and

190

they contain 4 acres; how much farther around is one than the Ans. 11.512 rods. other?

14. Mr. Thompson has a square yard containing In of an acre; he makes a gravel walk around it which occupies 15 of the whole yard; Ans. 4 feet 11 inches. what is the width of the walk?

15. A general, attempting to draw up his division in the form of a square, found he lacked 100 men to complete the square; he then received a reinforcement of five companies of 100 men each, and found he could increase the side of the square by 3 men and have 1 man remaining; how many men had he at first? Ans. 4125 men.

VOLUMES.

1. The volume of a sphere is 606,132 cubic feet; required its diameter.

2. The edge of a cube is 6 feet; what is the volume of a sphere that Ans. 113.0976 cubic feet. may be inscribed within it?

3. I have a cistern in the form of the frustum of a cone, its top diameter being 12 feet, its bottom diameter 9 feet, and its depth 5 feet; how many barrels of water will it contain? Ans. 103.515 barrels.

4. Bunker Hill Monument is 220 feet high, 30 feet square at the base, and 15 feet at the vertex; what is its volume? Ans. 115500 cubic ft.

5. Mr. Wilson has a pond which covers 100 acres, the average depth being 10 feet; how many cubic feet of water does it contain?

Ans. 43560000 cubic feet.

6. A man has a log of wood 20 ft. long, the larger end being 3 ft. in diameter, and the smaller 2 ft.; required the contents of the largest square stick, 20 ft. long, that can be sawed out of it. Ans. 631 cubic feet.

7. A bushel measure is 184 inches in diameter and 8 inches deep; what should be the dimensions of a measure of similar form to contain Ans. Diameter, 74 inches; depth, 32 inches.

8. Mr. Benson can dig a shaft 5 feet each way in one day; how long Ans. 64 days. will it take him to dig a shaft 20 feet each way?

9. A man has a square garden 100 feet long, and wishes to make a gravel walk half-way around it; what will be the width of the walk if Ans. 29.289 feet. it takes up one-half of the garden?

10. A wishes to enclose his garden, which is 100 feet long and 80 feet wide, with a ditch 4 feet wide; how deep must it be dug that the soil taken out may raise the surface 1 foot?

GEOMETRY.

11. A cubic foot of brass is to be drawn into a wire 10 of an inch in diameter; required the length of the wire, supposing there is no loss of metal in the process. Ans. 31.252 miles.

12. Mr. Bonnycastle mentions a globe whose volume and surface are represented by the same number; what was the diameter of this globe?

Ans. 6.

13. Mr. Haswell requires the weight of an iron shell 4 inches in diameter, the thickness of the metal being 1 inch, estimating a cubic inch of iron at 1 of a pound. Ans. 7.3304 pounds.

14. Bunker Hill Monument is 220 feet high, the lower base being 30 feet square, the upper 15 feet square; through its centre runs a cylindrical opening 15 feet in diameter at the bottom and 11 feet at the top; how many cubic feet of material in the monument?

Ans. 86068,444 cubic feet.

15. A gentleman has a bowling-green 300 feet long and 200 feet broad, which he wishes to raise I foot higher by means of the earth that is to be taken from a ditch that is to go around it; to what depth must the ditch be dug, supposing its breadth to be 8 feet?

Ans. 7 feet 3.21 inches.

16. A man having a garden 100 feet long and 80 feet broad, wishes to make a gravel walk half-way around it; what will be the width of the walk if it takes up one-half of the garden? Ans. 25,9688 feet.

17. Three persons having bought a sugar loaf, want to divide it equally among them by sections parallel to the base; what is the altitude of each person's share, supposing the loaf is a cone 20 inches high?

Ans. 13.867 upper part; 3.604 middle; 2.528 lower.

Suggestion .- Solve it by the principle of similar cones being to each other as the cubes of their altitudes.

Note. - Several of these problems are from the old writers on Mensuration. For more methods and exercises, see Bonnycastle's and Haswell's works on Mensuration.

ELEMENTS OF TRIGONOMETRY.

INTRODUCTION.

LOGARITHMS.

- 1. Logarithms are a species of numbers used to abbreviate Multiplication, Division, Involution, and Evolution.
- 2. The logarithm of a number is the exponent denoting the power to which a fixed number must be raised in order to produce the first number.
- 3. This fixed number is called the base of the system. The base of the common system is 10.
 - 4. Raising 10 to different powers, we have,

$$10^{0} = 1$$
 ; hence, 0 is the log of 1; $10^{1} = 10$ " 1 " 10; $10^{2} = 100$ " 2 " 100; $10^{3} = 1000$ " 3 " 1000;

etc.

5. From this we have the following principles:

Prin. 1. The logarithm of a number between 1 and 10 is between 0 and 1, and is, therefore, a decimal.

PRIN. 2. The logarithm of a number between 10 and 100 is between 1 and 2, and is, therefore, 1 and a decimal. Thus, it has been found that the log, of 76 is 1.880814.

Prin. 3. The logarithm of a number between 100 and 1000 is between 2 and 3, and is, therefore, 2 and a decimal. Thus, the log. of 458 is 2.660865.

6. When the logarithm consists of an integer and a decimal,

INTRODUCTION

- 23

the integer is called the *characteristic*, and the decimal part the *mantissa*. Thus, in 2.660865 the 2 is the characteristic, and .660865 is the mantissa.

PROPERTIES OF LOGARITHMS.

PRIN. 1.—The characteristic is always one less than the number of integral places in the number.

For, from Art. 4, we see that the log. of 100 is 2, the log. of 1000 is 3, and of any number between 100 and 1000 it is 2 and a decimal; hence, the characteristic is one less than the number of integral places.

PRIN. 2.—The logarithm of the base is 1, and the logarithm of 1 is

For, since $10^1 = 10$, the log. of 10 is 1; and since $10^0 = 1$, the logarithm of 1 is 0.

PRIN. 3.—The characteristic of the logarithm of a decimal is negative, and is numerically one greater than the number of ciphers between the decimal point and the first significant figure.

For, if we raise the base, 10, to powers which give decimals, we will have,

$$10^{\circ} = 1$$
 ; hence, $\log 1 = 0$; $10^{-1} = .1$ " $\log .1 = -1$; $10^{-2} = .01$ " $\log .01 = -2$; $10^{-3} = .001$ " $\log .001 = -3$; etc.

which proves the principle. Thus, the log, of .458 is I.660865.

PRIN. 4.—The logarithm of the product of two numbers is equal to the sum of the logarithms of those numbers.

For, let M and N be any two numbers, and m and n their logarithms; then we shall have, according to the definition,

$$10^m = M.$$
 $10^n = N.$

Multiplying these equations, member by member, we have,

$$10^{m+n} = M \times N.$$

Hence,
$$\log (M \times N) = m + n$$
; or, $= \log M + \log N$.

Prin. 5.—The logarithm of the quotient of two numbers equals the difference of the logarithms of those numbers.

For, from the definition, we have,

$$10^m = M$$
, $10^n = N$.

Dividing the first by the second, we have,

$$10^m - n = \frac{M}{N}.$$

Hence, $\log\left(\frac{M}{N}\right) = m - n$, or, $= \log M - \log N$.

PRIN. 6.—The logarithm of any power of a number is equal to the logarithm of the number multiplied by the exponent of the power.

For, since

$$10^m = M$$
,

if we raise both members to the nth power, we have,

$$10^{mn} = M^n$$
.

Hence, $\log M^n = mn$, or, $= \log M \times n$.

PRIN. 7.—The logarithm of the root of any number is equal to the logarithm of the number divided by the index of the root.

For, since

$$10^m = M$$
,

if we take the nth root of both members, we have,

$$10^{\frac{m}{n}} = \sqrt[n]{M}.$$

ence,
$$\log \sqrt{M} = \frac{m}{n}$$
, or, $\log M + n$.

Prin. 8.—The logarithm of the product of any number multiplied by 10 is equal to the logarithm of the number increased by 1.

Suppose $\log M = m$; then, by Prin. 4,

$$\log (M \times 10) = \log M + \log 10$$
. But $\log 10 = 1$;

Hence,
$$\log (M \times 10) = m + 1$$
.

Thus,
$$\log (76 \times 10) = 1.880814 + 1$$
; or, $\log 760 = 2.880814$.

PRIN. 9.—The logarithm of the quotient of any number divided by 10 is equal to the logarithm of the number diminished by 1.

Suppose $\log M = m$; then, by Prin. 5, $\log (M \div 10) = \log M - \log 10$; from which $\log (M \div 10) = m - 1$.

Thus, $\log (458 \div 10) = 2.660865 - 1$; or $\log 45.8 = 1.660865$.

7. The following examples will illustrate Principles 1, 3, 8, and 9.

log 234 is 2.369216, log 23.4 " 1.369216, log 2.34 " 0.369216, log .234 " 1.369216, log .0234 " 2.369216.

From this, we see that when we change the place of the decimal point we change the characteristic, but do not change the decimal part of the logarithm.

The minus sign is written over the characteristic, showing that it only is negative.

TABLE OF LOGARITHMS.

- 8. A Table of Logarithms is a table by means of which we can find the logarithms of numbers, or the numbers corresponding to given logarithms.
- 9. In the annexed table the entire logarithms of the numbers up to 100 are given. For numbers greater than 100 the mantissa alone is given; the characteristic being found by Prin. 1.
- 10. The numbers are placed in the column on the left, headed N; their logarithms are opposite, on the same line. The first two figures of the mantissa are found in the first column of logarithms.
- 11. The column headed D shows the average differences of the ten logarithms in the same horizontal line. This difference is found by subtracting the logarithm in column 4 from that in column 5, and is very nearly the mean or average difference.

TO FIND THE LOGARITHM OF ANY NUMBER.

12. To find the logarithm of a number of one or two figures.

Look on the first page of the table, in the column headed N, and opposite the given number will be found its logarithm. Thus,

the logarithm of 25 is 1.397940, " " 87 is 1.939519.

13. To find the logarithm of a number of three figures.

Look in the table for the given number; opposite this, in column headed 0, will be found the decimal part of the logarithm, to which we prefix the characteristic 2, Prin. 1. Thus,

the logarithm of 325 is 2.511883, " " 876 is 2.942504.

14. To find the logarithm of a number of FOUR figures.

Find the three left-hand figures in the column headed N, and opposite to these, in the column headed by the fourth figure, will be found four figures of the logarithm, to which two figures from the column headed 0 are to be prefixed. The characteristic is 3, Prin. 1. Thus,

the logarithm of 3456 is 3.538574,
" " 7438 is 3.871456.

15. In some of the columns, small dots are found in the place of figures; these dots mean zeros, and should be written zeros. If the four figures of the logarithm fall where zeros occur, or if, in passing back from the four figures found to the zero column, any of these dots are passed over, the two figures to be prefixed must be taken from the line just below. Thus,

the logarithm of 1738 is 3.240050, " 2638 is 3.421275.

16. To find the logarithm of a number of more than four figures.

Place a decimal point after the fourth figure from the left hand, thus changing the number into an integer and a decimal. Find the mantissa of the entire part by the method just given. Then

INTRODUCTION.

from the column headed D take the corresponding tabular difference, multiply it by the decimal part, and add the product to the mantissa already found; the result will be the mantissa of the given number. The characteristic is determined by Prin. 1.

If the decimal part of the product exceeds .5, we add 1 to the entire part; if less than .5, it is omitted.

EXAMPLES.

1. Find the logarithm of 234567.

Solution.—The characteristic is 5, Prin. 1. Placing a decimal point after the fourth figure from the left, we have 2345.67. The decimal part of the logarithm of 2345 is .370143; the number in column D is 185; and $185 \times .67 = 123.95$, and since .95 exceeds .5, we have 124, which, added to .370143, gives .370267; hence, log 234567 = 5.370267.

0	Find the logarith	m of	4567		Ans. 3.659631.
3.	Find the logarith	m of	3586.	//	Ans. 3.554610.
4.	Find the logarith	m of	11806.	7/ 11/2	Ans. 4.072102.
	Find the logarith				Ans. 1.674769.
6	Find the logarith	m of	29.337.	B 117	Ans. 1.467416.

- 17. To find the number corresponding to a given logarithm.
- 1. Find the two left-hand figures of the mantissa in the column headed 0, and the other four, if possible, in the same or some other column, on the same line; then, in column N, opposite to these latter figures, will be found the three left-hand figures, and at the top of the page the other figure of the required number.
- 2. When the exact mantissa is not given in the table, take out the four figures corresponding to the next less mantissa in the table; subtract this mantissa from the given one; divide the remainder, with ciphers annexed, by the number in column D, and annex the quotient to the four figures already found.
- 3. Make the number thus obtained correspond with the characteristic of the given logarithm, by pointing off decimals or annexing ciphers.

EXAMPLES.

1. Find the number whose logarithm is 5.370267.

The tabular difference is 185

The quotient is 185)124.00(.67

Hence, the required number is . 234567.

Note.—If the characteristic had been 2, the number would have been 234.567; if it had been 7, the number would have been 23456700; if it had been 2, the number would have been .0234567, etc.

2. Find the number whose logarithm is 3.659631.

Ans. 4567.

3. Find the number whose logarithm is 2.554610.

Ans. 358.6.

4. Find the number whose logarithm is 1.072102.

Ans. 11.806.

Find the number whose logarithm is 2.674769.

Ans. .04729.

6. Find the number whose logarithm is 3.065463.

Ans. .0011627.

MULTIPLICATION BY LOGARITHMS.

18. From Prin. 4, for the multiplication of numbers by means of logarithms, we have the following

Rule.—Find the logarithms of the factors, take their sum, and find the number corresponding to the result; this number will be the required product.

Note.—The term sum is used in its algebraic sense. Hence, when any of the characteristics are negative,—the mantissa is always positive,—we take the difference between the sums of the positive and negative characteristics, and prefix to it the sign of the greater. If any thing is to be carried from the addition of the mantissas, it must be added to a positive characteristic, or subtracted from a negative one.

EXAMPLES.

1. Multiply 35.16 by 8.15.

 $\log 35.16 = 1.546049$ SOLUTION.

log 8.15 = 0.911158

2,457207

457125

Product, 286.554

152 82.00(.54

2. Find the product of .7856, 31.42.

Ans. 24.6835.

3. Find the product of 31.42, 56.13, and 516.78.

Ans. 911393.7.

4. Find the product of 31.462, .05673, and .006785.

Ans. 01211168.

5. Product of .06517, 2.16725, .000317, and 42.1234

Ans. .001886.

6. Product of 2.3456, .00314, 123.789, .00078, and 67.105.

Ans. .04772076.

DIVISION BY LOGARITHMS.

19. From Prin. 5, to divide by means of logarithms, we have the following

Rule.-Find the logarithms of the dividend and divisor, subtract the latter from the former, and find the number corresponding to the result: this number will be the required quotient.

Note. The term subtract is here used in its algebraic sense; hence, we must subtract according to the principles of algebra.

EXAMPLES.

1. Divide 783.5 by 6.25.

 $\log 783.5 = 2.894039$ SOLUTION.

 \log 6.25 = 0.795880

2.098159

.097951

Quotient,

125.36

346)208(6

Ans. 42.8. 2. Divide 272.636 by 6.37. 3, Divide 50.38218 by 67.8. Ans. .7431. 4. Divide 155 by .0625. Ans. 2480.

ARITHMETICAL COMPLEMENT.

20. The operation of division when combined with multiplication is somewhat simplified by using the principle of the arithmetical complement.

21. The Arithmetical Complement of a logarithm is the result arising from subtracting the logarithm from 10. Thus, the arithmetical complement of the logarithm 5.623427 is 10-5.623427, or 4.376573.

22. The arithmetical complement may be written directly from the table, by subtracting each figure of the logarithm from 9, except the right-hand figure, which must be taken from 10. This is the same as subtracting the logarithm from 10.

23. We will now prove that the difference between two logarithms is equal to the first logarithm, plus the arithmetical complement of the second, minus 10.

Let a = the first logarithm,

b =the second logarithm,

c = 10 - b = arith. comp. of b. and

The difference is a-b

-b = c - 10. But.

which proves the principle.

a-b = a+c-10

24. Hence, to divide by means of the arithmetical complement,

we have the following

Rule.—Add the arithmetical complement of the legarithm of the divisor to the logarithm of the dividend, subtract 10, and find the number corresponding to the difference, this number will be the required quotient.

EXAMPLES.

1. Divide 856.3 by 45.32.

INTRODUCTION.

11

Solution.	log 856.3	٠.		2.932626
*	(a. c.) log 45.32	*	**	8.343710
Quotient.	18,8945			1.276336

2. Divide 0.3156 by 78.35.

Quotient,

7.499137 log 0.3156 . 8.105961 (a. c.) log 78.35 3.605098

Quotient. .004028

Ans. .204519. 3. Divide 3.7521 by 18.346. Ans. 1573,02. 4. Divide 483.72 by .30751.

5. Multiply 32.16 by 7.856, and divide the product by 45.327.

Ans. 5.574.

6. Divide the product of 31.57 and 123.4 by the product of Ans. 389.8884. 316.2 and .0316,

7. Find by logarithms the first term of the proportion, Ans. 1.11237. x: 73.15:: 48.16: 3167.

INVOLUTION BY LOGARITHMS.

25. From Prin. 6, to raise a number to any power, we have the

RULE .- Find the logarithm of the number, multiply it by the exponent of the power, and find the number corresponding to the result.

1. Find the 4th power of 45.

SOLUTION.

 $\log 45 = 1,653213$

Power.

2. Find the cube of 0.65.

3. Find the 6th power of 1.037.

4. Find the 7th power of .4797.

Ans. 0.2746.

Ans. 1.243.

Ans. 0.005846.

EVOLUTION BY LOGARITHMS.

26. From Prin. 7, to extract any root of a number, we have the following

RULE .- I. Find the logarithm of the number, divide it by the index of the root, and find the number corresponding to the result.

II. If the characteristic is negative and not divisible by the index of the root, add to it the smallest negative number that will make it divisible, prefixing the same number with a plus sign to the mantissa.

EXAMPLES.

1. Find the square root of 576.

SOLUTION.

 $\log 576 = 2.760422$

 $2.760422 \div 2 = 1.380211$

Hence, the root is 24.

2. Find the fourth root of .325.

SOLUTION.

 $\log .325 = 1.511883 = 4 + 3.511883$.

 $(4+3.511883) \div 4 = 1.877971$ Then

Hence, the quotient is, .75504.

3. Find the fifth root of .0625.

Ans. .574348. Ans. 1.9129.

4. Find the cube root of 7. 5. Find the fifth root of 5.

Ans. 1.3797.

6. Find the tenth root of 8764.5.

Ans. 2.479.

CALCULATION OF LOGARITHMS

The pupil will by this time naturally inquire how these logarithms are calculated. This we have not room to explain here; in fact, an explanation of the modern methods would be almost too difficult for the majority of pupils who study this book. Only a general idea can here be given.

In computing logarithms, it is only necessary to calculate the logarithms of prime numbers, since the logarithms of composite numbers may be obtained by adding the logarithms of their prime factors.

The logarithms of the prime numbers were first computed by com-

paring the geometrical and arithmetical series, 1, 10, 100, etc., and 0, 1, 2, etc., and finding geometrical and arithmetical means; the arithmetical mean being the logarithm of the corresponding geometrical mean. This method was exceedingly laborious, involving so many multiplications and extractions of roots.

The method now generally used is that of series, by which the computations are much more easily made. The following formula is derived by algebraic reasoning.

$$\log (1+x) = A\left(\frac{x}{1} - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \text{etc.}\right)$$

In this the quantity A is called the modulus, which in the Napierian system is unity. The series, when A is one, put in a more convenient form, becomes,

log.
$$(z+1) - \log z = 2\left(\frac{1}{2z+1} + \frac{1}{3(2z+1)^3} + \frac{1}{5(2z+1)^6} + \text{etc.}\right)$$

From which, knowing the logarithm of any number, we readily find the logarithm of the next larger number. The pupil will be interested in finding logarithms by this formula. Begin with 2, in which z=1.

The logarithm found will be the Napierian logarithm, and this multiplied by 0.434294 will give the common logarithm.

UNIVERSIDAD AUTÓNO DIRECCIÓN GENERAL

PLANE TRIGONOMETRY.

DEFINITIONS AND PRIMARY PRINCIPLES.

- 1. PLANE TRIGONOMETRY is the science which treats of the solution of plane triangles.
- 2. The Solution of a triangle is the operation of finding the unknown parts when a sufficient number of the known parts are given.
- 3. In every triangle there are six parts; three sides and three angles. These parts are so related that when three of the parts are given, one being a side, the other parts may be found.
- 4. An angle is measured, as we have previously seen, by the are included between its sides, the centre of the circumference being at the vertex of the angle.
- 5. For measuring angles, as has already been explained, the circumference is divided into 360 equal parts, called degrees, each degree into 60 equal parts, called minutes, etc.
- 6. A QUADRANT is one-fourth of the circumference of a circle; hence, if two lines be drawn through the centre of a circle at right angles to each other, they will divide the circumference into four quadrants. Each quadrant contains 90°.
- 7. The COMPLEMENT of an arc is 90° minus the arc; thus, DC is the complement of BC; also, the angle DOC is the complement of BOC.
- - 8. The SUPPLEMENT of an arc is 180° minus the arc; thus,

paring the geometrical and arithmetical series, 1, 10, 100, etc., and 0, 1, 2, etc., and finding geometrical and arithmetical means; the arithmetical mean being the logarithm of the corresponding geometrical mean. This method was exceedingly laborious, involving so many multiplications and extractions of roots.

The method now generally used is that of series, by which the computations are much more easily made. The following formula is derived by algebraic reasoning.

$$\log (1+x) = A\left(\frac{x}{1} - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \text{etc.}\right)$$

In this the quantity A is called the modulus, which in the Napierian system is unity. The series, when A is one, put in a more convenient form, becomes,

log.
$$(z+1) - \log z = 2\left(\frac{1}{2z+1} + \frac{1}{3(2z+1)^3} + \frac{1}{5(2z+1)^6} + \text{etc.}\right)$$

From which, knowing the logarithm of any number, we readily find the logarithm of the next larger number. The pupil will be interested in finding logarithms by this formula. Begin with 2, in which z=1.

The logarithm found will be the Napierian logarithm, and this multiplied by 0.434294 will give the common logarithm.

PLANE TRIGONOMETRY.

DEFINITIONS AND PRIMARY PRINCIPLES.

- 1. PLANE TRIGONOMETRY is the science which treats of the solution of plane triangles.
- 2. The Solution of a triangle is the operation of finding the unknown parts when a sufficient number of the known parts are given.
- 3. In every triangle there are six parts; three sides and three angles. These parts are so related that when three of the parts are given, one being a side, the other parts may be found.
- 4. An angle is measured, as we have previously seen, by the are included between its sides, the centre of the circumference being at the vertex of the angle.
- 5. For measuring angles, as has already been explained, the circumference is divided into 360 equal parts, called degrees, each degree into 60 equal parts, called minutes, etc.
- 6. A QUADRANT is one-fourth of the circumference of a circle; hence, if two lines be drawn through the centre of a circle at right angles to each other, they will divide the circumference into four quadrants. Each quadrant contains 90°.
- 7. The COMPLEMENT of an arc is 90° minus the arc; thus, DC is the complement of BC; also, the angle DOC is the complement of BOC.
- - 8. The SUPPLEMENT of an arc is 180° minus the arc; thus,

PLANE TRIGONOMETRY.

15

AE is the supplement of the arc BDE; also, the angle AOE is the supplement of the angle BOE.

9. In Trigonometry, instead of comparing the angles of triangles, or the arcs which measure them, we compare certain lines, called *functions* of the arcs. A function of a quantity is something depending upon the quantity for its value. These functions are the sine, cosine, tangent, cotangent, secant, and cosecant.

10. Thus, instead of reasoning with the angle ACB, or the arc

AB, which measures it, we draw the perpendicular AD, and use the lines AD and CD. The line AD is called the *sine* of the arc or angle; the line CD is called the *cosine* of the arc or angle.

11. If we draw BE perpendicular to CB, meeting CA produced in E, the line BE is called the *tangent* of the angle, and the line CE is called the *secant*.

12. In comparing the sides and angles, these lines, we say, are used instead of the angles or the arcs. The necessity for such

lines is evident, since we could not compare the sides, which are straight lines, with the angles, or the curve lines, which measure them.

We will now represent these lines in the first and second quadrants.

13. The Sine of an arc is the perpendicular let fall from one extremity of the arc on the diameter which passes through the other extremity.

Thus, CD is the sine of the arc AC.

arc AC.

14. The COSINE of an arc is the sine of its complement; or it is the distance between the foot of the sine and the centre of the circle; thus, CE or OD is the cosine of the

to the radius at one extremity of the arc, and limited by a line passing through the centre of the circle and the other extremity; thus, AT is the tangent of AC.

16. The Cotangent of an arc is equal to the tangent of the

15. The TANGENT of an arc is a line which is perpendicular

16. The Cotangent of an arc is equal to the tangent of the complement of the arc; thus, BT' is the cotangent of AC.

17. The Secant of an arc is a line drawn from the centre of the circle through one extremity of the arc, and limited by a tangent at the other extremity; thus, OT is the secant of AC.

18. The COSECANT of an arc is the secant of the complement of the arc; thus, OT' is the cosecant of AC.

19. The sine, cosine, tangent, cotangent, etc. of an arc are indicated as follows:

$$\sin AC$$
; $\tan AC$; $\sec AC$; $\cot AC$; $\cot AC$.

20. Principles.—From the definitions now given, we can readily derive the following simple principles.

1. The sine of an arc equals the sine of its supplement, and also the cosine of an arc equals the cosine of its supplement.

Dem.—Take the arc ABF; its sine is FG, its supplement is FH, and the sine of its supplement is FG. Hence, its sine equals the sine of its supplement. Its cosine is GO, which is also the cosine of FH. Hence, etc.

2. The tangent and cotangent of an arc are respectively equal to the tangent and cotangent of the supplement of the arc.

DEM.—The tangent of the arc ABF is AT''', and the tangent of its supplement FH is HT'', and, by similar triangles, it may be shown that AT''' equals HT''; therefore, etc.

3. The secant and cosecant of an arc are respectively equal to the secant and cosecant of the supplement of the arc.

This may be demonstrated in a manner quite similar to those above. Let the pupil be required to show it.

 If a equals any arc or angle, then we shall have, from the definitions,

PLANE TRIGONOMETRY.

17

 $\sin a = \cos (90^{\circ} - a)$

 $\tan a = \cot (90^{\circ} - a)$

 $\sec a = \csc (90^{\circ} - a)$

NATURAL SINES, COSINES, ETC.

21. The length of these trigonometrical lines may be expressed in numbers, differing, of course, as the radius of the circle is larger or smaller. If the radius is regarded as unity, or 1, we have what are called natural sines, cosines, etc. The method of calculating these sines, cosines, etc. will be explained hereafter.

The operation of multiplying and dividing by these natural sines being long and tedious, it has been found more convenient to use logarithmic sines, which we will now explain.

TABLE OF LOGARITHMIC SINES.

22. A LOGARITHMIC SINE, COSINE, TANGENT, OF COTANGENT is the logarithm of the sine, cosine, tangent, or cotangent of an arc of a circle whose radius is 10,000,000,000.

23. A Table of Logarithmic Sines is a table containing the logarithmic sine, cosine, tangent, and cotangent of arcs.

24. The table of logarithmic sines may be calculated from a table of natural sines, as will be explained hereafter. In the table, the degrees are given at the top and bottom of the page, and the minutes at the sides, in the column headed M.

25. The column headed D contains the increase or decrease for 1 second. This is found by subtracting the logarithmic sine, etc. of an arc from that next exceeding it by 1 minute, and dividing the difference by 60.

26. To find the logarithmic sines, cosines, etc. of arcs or angles.

1. When the arc is expressed in degrees, or in degrees and minutes. If the angle is less than 45°, look for the degrees at the top of the page, and for the minutes in the left-hand column; then, opposite to the minutes, on the same horizontal line, in the column headed

Sine, will be found the logarithmic sine; in that headed Cosine will be found the logarithmic cosine, etc. Thus,

log sin 23° 35′ log tan 23° 35′

9.602150

9.640027

If the angle exceeds 45°, look for the degrees at the bottom of the page, and for the minutes in the right-hand column; then, opposite to the minutes, in the same horizontal line, in the column marked at the bottom Sine, will be found the logarithmic sine, etc. Thus,

log cos 65° 24′

9.619386

log tan 65° 24'

10.339290

2. When the arc contains seconds.—Find the logarithmic sine, etc. as before; then multiply the corresponding number found in column D by the number of seconds, and add the product to the preceding logarithm for the sines or tangents, and subtract it for cosines or cotangents.

We subtract for cosine and cotangent, because the greater the arc the less the cosine or cotangent. In multiplying the tabular difference by the number of seconds, we observe the same rule for the decimal point as in logarithms. If the arc is greater than 90°, we find the sine, cosine, etc. of its supplement.

EXAMPLES.

1. Find the logarithmic sine of 36° 24′ 42′

SOLUTION.

log sin 36° 24′,

9.773361

Tabular difference,

, 2.00

No. of seconds,

- DI

Product, log sin 36° 24′ 42″, 119.70 to be added,

9.773481

120

2. Find the logarithmic cosine of 64° 30′ 30″.

17 #

SOLUTION.

log cos 64° 30',

9.633984

Tabular difference,

4.41

No. of seconds,

Product,

132.30 to be subtracted,

132

log cos 64° 30′ 30″,

9.633852

3. Find the logarithmic tangent of 120° 15′ 24".

SOLUTION.

180° 00′ 00′

The given arc,

120 15 24

Supplement,

59 44 36

log tan 59° 44',

No. of seconds,

10.233905

Tabular difference,

36 to be added,

174.24

log tan 120° 15′ 24″,

10.234079

- 4. Find the logarithmic sine of 40° 40′ 40′. Ans. 9.814117.
- 5. Find the logarithmic cosine of 140° 30′ 20".

Ans. 9.887441.

6. Find the logarithmic tangent of 85° 25′ 45".

Ans. 11.097200.

7. Find the logarithmic cotangent of 144° 44' 28".

27. To find the arc corresponding to any logarithmic sine, cosine, tangent, or cotangent.

1. Look in the proper column of the table for the given logarithm; if found there, and the name of the function be at the head of the column, take the degrees at the top, and the minutes on the left; but if the name of the function is at the foot of the column, take the degrees at the bottom, and the minutes on the right.

2. If the given logarithm is not exactly given in the table,

then take the next less logarithm, subtract it from the given logarithm, and divide the remainder by the corresponding tabular difference; the quotient will be seconds, which must be added to the degrees and minutes corresponding to the logarithm taken from the table, for sines and tangents, and subtracted for cosines and colangents.

EXAMPLES.

1. Find the arc whose logarithmic sine is 9.617033.

SOLUTION.

Given log sine.

9.617033

Next less in table.

9.616894

Tabular difference, 4.63)

139.00(30, to be added.

Hence, the arc or angle is 24° 27′ 30".

2. Find the arc whose logarithmic cosine is 9.704682.

SOLUTION.

Given log cosine,

9.704682 9.704610

Next less in table, Tabular difference, 3.58)

72.00(20, to be subtracted.

Hence, the arc or angle is 59° 33' 40".

3. Find the arc whose logarithmic sine is 9.438672.

Ans. 15° 56' 14'

4. Find the arc whose logarithmic cosine is 9.634520.

Ans. 64° 27' 47".

Find the arc whose logarithmic tangent is 10.753246.

Ans. 79° 59' 24".

6. Find the arc whose logarithmic cotangent is 11.449852.

Ans. 2º 1' 40".

28. Having learned how to find logarithmic sines, cosines, etc., we will next demonstrate some theorems for the solution of triangles.

THE THEOREMS OF TRIGONOMETRY.

29. The Theorems of Trigonometry express the relation between the sides and trigonometrical functions of the angles of triangles.

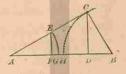

30. We give five theorems, the first three relating to triangles in general, the others to right-angled triangles.

THEOREM I.

31. In any plane triangle, the sides are proportional to the sines of the opposite angles.

Let ABC be a plane triangle; then will $CB: CA:: \sin A: \sin B$.

For, with A as a centre, and a radius AE equal to BC, describe the arc EG, and draw the perpendicular EF. With B as a centre,

and the equal radius BC, describe the arc CH, and draw the perpendicular CD; then will CD be the sine of the angle B, and EF be the sine of the angle A, to the same radius. Now, by similar triangles (B. III. Th. X.),

AE:AC::EF:CD.

But AE equals CB, EF is $\sin A$, and CD is $\sin B$. Hence, $BC: AC: \sin A: \sin B$.

In a similar manner, it may be shown that

· AC: AB:: sin B:: sin C.

Therefore, etc.

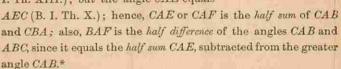

THEOREM II.

32. In any plane triangle, the sum of any two sides is to their difference as the tangent of half the sum of the opposite angles is to the tangent of half their difference.

Let ABC be any plane angle; then will $BC + AC:BC - AC:\tan\frac{1}{2}(A+B):\tan\frac{1}{2}(A-B)$.

For, produce AC to D, making CD equal to CB, and draw BD; take CE equal to AC, draw AE, and produce it to F; then AD is the sum and BE the difference of the two sides AC and BC.

The sum of the angles CAE and AEC equals the sum of CAB and CBA, both sums being equal to 180° minus ACB (B. I. Th. XIII.); but the angle CAE equals

The angle CDF equals CBD, since CB equals CD; also, CAE, which equals AEC, is equal to the vertical angle FEB; hence, the third angles of the triangles, AFD and EFB, are equal, and, therefore, AF is perpendicular to BD; consequently, if then we regard AF as the radius, FD will be the tangent of DAF, and FB will be the tangent of FAB. Now, by similar triangles,

$$AD: EB:: FD: FB: \text{ or,}$$
 $CB + AC: CB - AC:: \tan \frac{1}{2} (A + B): \tan \frac{1}{2} (A - B).$

THEOREM III.

33. In any plane triangle, if a line is drawn from the vertical angle perpendicular to the base, then the whole base will be to the sum of the other two sides as the difference of those sides is to the difference of the segments of the base.

Let ABC be a triangle, and CD perpendicular to the base; then will AB:AC+BC:AC-BC:AD-DB.

*This principle is thus proven:—Let
$$a$$
 and b be any two quantities; then the half sum is $\frac{a+b}{2}$, and the half difference is $\frac{a-b}{2}$; and $a-\frac{a+b}{2}=\frac{a-b}{2}$; that is, the greater values the half sum equals the half difference.

For, from Th. VI. Book III.,

$$AC^2 = \overline{AD^2} + \overline{DC^2},$$

and

$$\overline{BC^2} = \overline{BD^2} + \overline{DC^2}.$$

Subtracting, $\overline{AC^2} - \overline{BC^2} = \overline{AD^2} - \overline{BD^2}$.

Hence (B. III. Th. V. C. 2),

$$(AC+BC)\times (AC-BC)=(AD+BD)\times (AD-BD);$$

therefore, AD + DB : AC + BC : AC - BC : AD - DB.

Therefore, etc.

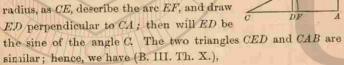

THEOREM IV.

34. In any right-angled plane triangle, radius is to the sine of either angle as the hypothenuse is to the side opposite.

Let CAB be a triangle right-angled at A, and denote the radius by R: then will

$$R:\sin C::CB:AB.$$

For, from the point C as a centre and any radius, as CE, describe the arc EF, and draw ED perpendicular to CA; then will ED be

 $R : \sin C : : CB : BA$.

Therefore, etc.

or,

Cor. It may also be shown that roulius is to the cosine of either acute angle as the hypothenuse is to the side adjacent.

THEOREM V.

35. In any right-angled plane triangle, radius is to the tangent of either acute angle as the side adjacent is to the side opposite.

Let CAB be a triangle right-angled at A; then will

For, with C as a centre and any radius CD, describe the arc

DE, and draw DF perpendicular to CA; FD will be the tangent of the angle C. The triangles CDF and CAB are similar; hence,

R: tan C:: CA: AB.

Therefore, etc.

or,

Cor. It may also be shown that radius is to cotangent of either angle, as side opposite is to side adjacent.

- 36. THE SOLUTION OF A TRIANGLE is the process of finding the anknown parts when a sufficient number of the parts are given.
- 37. There are six parts in a plane triangle, and three of theseone of the three being a side-must be given to find the other parts.
- 38. If the angles alone were given, it is clear that the sides could not be determined, since there could be an indefinite number of triangles having their angles respectively equal.
 - 39. There are four cases, as follows:
 - 1. When two angles and a side are given.
 - 2. When two sides and an angle are given.
 - 3. When two sides and the included angle are given.
 - 4. When the three sides are given.

CASE I.

40. Given two angles and one side, to find the remaining parts.

METHOD.-We subtract the sum of the given angles from 180° to find the third angle, and then find the sides by Theorem I.

EXAMPLES.

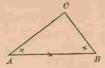

1. In a triangle ABC, there are given the angle $A = 32^{\circ} 24'$, the angle $B = 40^{\circ} 32'$, and the side AB = 240; required the other parts.

Solution.—Let ABC represent the triangle; then the sum of

A and $B = 72^{\circ} 56'$, and $C = 180^{\circ} - 72^{\circ} 56' = 107^{\circ} 04'$. Then, to find AC, we have,

 $AC:AB: \sin B: \sin C.$

Hence, $AC = AB \times \sin B \div \sin C$.

From which AC is readily found by multiplying 240 by the natural sine of B, and dividing by the natural sine of C. It is simpler, however, to use logarithms. To find AC, we add the log of AB and log sin B, and subtract log sin C, or add the arith, comp. of log sin C.

a. c. log sin C (107° 04′), 0.019558 log sin B (40° 32′), 9.812840 log AB (240), 2.380211

 $\log AC$, 2.212609 .; AC=163.158 To find the side BC, we have,

 $BC: AB::\sin A:\sin C:$

or, by logarithms,

a. c. log sin C (107° 04'), 0.019558

log sin A (32° 24'), 9.729024

log AB (240), 2.380211

 $\log BC$,

 $2.128793 \therefore BC = 134.522$

2. In the triangle ABC, there are given the angle $A=27^{\circ}$ 40′, the angle $C=65^{\circ}$ 45′, and the side AB=625, to find the other parts. $Ans. B=86^{\circ}$ 35′; BC=318.29; AC=684.266.

CASE II.

41. Given two sides and an angle opposite one of them, to find the remaining parts.

Метнор.—One of the required angles is found by Theorem I.

The third angle is found by subtracting the sum of the two from 180°; the third side is found by Case I.

EXAMPLES.

1. In the triangle ABC, there are given AC=200, CB=150, and the angle $A=44^{\circ}$ 26', to find the other parts.

Solution.—Let ABC be a triangle in which $A=44^{\circ}$ 26′, AC=200, and BC=150; then,

to find the angle B, we have,

 $\sin B : \sin A :: AC : BC,$ or, BC = (150) a. c. 7.823009 : AC = (200) 2.301030 $:: \sin A = (44^{\circ} 26')$ 9.845147 $: \sin B = (100)$ 9.969186

 $\therefore B = 68^{\circ} 40' 16''$, or, $111^{\circ} 19' 44''$

In this problem, if the side BC, opposite the given angle A, is shorter than the other given side AC, the solution will be ambiguous; for two triangles, ACB and ACB', may be formed, each of which will satisfy the conditions of the problem. Hence, the angle B found above may be either ABC or B'. But these, it will be seen, are supplements of each other; hence, in finding the angle corresponding to $\sin B$, we take the angle or its supplement.

In practice, there is often some circumstance to determine whether the angle is acute or obtuse. If the angle given is obtuse, the other angles must be acute, and there will be but one solution. If the side BC is equal to or greater than AC, there will be but one triangle.

In the given diagram above, the angle $ABC = 111^{\circ} 19' 44''$, and $AB'C = 68^{\circ} 40' 16''$; hence, the angle $ACB = 24^{\circ} 13' 16''$, and the angle $ACB' = 113^{\circ} 6' 16''$.

To find the side AB, we have,

 $AB: CB: : \sin ACB: \sin A;$

from which, by logarithms, we find AB = 88.085. To find the side AB', we have,

 $AB': CB':: \sin ACB': \sin A;$

from which, by logarithms, we find AB' = 197.484.

2. In a triangle ABC there are given AB 45.96, BC 62.50, and the angle A 79° 21'; find the remaining parts.

Ans.
$$C = 46^{\circ} 16' 38''$$
; $B = 54^{\circ} 22' 22''$; $AC = 51.69$.

(There is no ambiguity, since the side BC is greater than AC.)

3. In a triangle ABC there are given BC = 15.71, AC = 21.12. and the angle $A=27^{\circ}$ 50'; find the other parts.

Ans.
$$C = 113^{\circ} 17' 13''; B = 38^{\circ} 52' 47''; AB = 30.906.$$

or, $C = 11^{\circ} 2' 47''; B = 141^{\circ} 7' 13''; AB = 6.447.$

CASE III.

42. Given two sides and the included angle, to find the remaining parts. Метнор.—We find the sum of the two angles by subtracting the given angle from 180°, and divide this by 2 for the half sum. We then find the half difference, by Theorem II. Having found the half sum and half difference of the two angles, we find the greater angle by adding the half difference to the half sum; and the less by subtracting the half difference from the half sum. The third side is found by Theorem I.

EXAMPLES.

1. In the triangle ABC, let BC = 680, AC = 460, and the in cluded angle 84°; required the other parts.

Solution.—Let ABC represent the triangle, AC = 460.

$$BC = 680$$
, and the angle $C = 84^{\circ}$. Then,
 $AC + BC = 460 + 680 = 1140$; $BC - AC =$

$$680 - 460 = 220$$
. $A + B = 180^{\circ} - 84^{\circ} =$

96°; hence, half sum = 48°. The half difference we find by the following proportion.

:
$$BC - AC$$
 220 . 2.342423
:: $\tan \frac{1}{2} (A + B)$ 48° . 10.045563

:
$$\tan \frac{1}{2} (A - B)$$
 12° 5′ 49″ 9.331081

Hence,
$$A = 60^{\circ} 5' 49''$$
; and $B = 35^{\circ} 54' 11''$.

The other side, found by Theorem I., equals 783.733.

2. Given two sides of a plane triangle 240 and 360, and the included angle 68° 36'; required the other parts.

Ans. 72° 02′ 26; 39° 21′ 34″; 352.349.

CASE IV.

43. Given the three sides of a plane triangle, to find the angles.

Метнор.—Let fall a perpendicular upon the greater side from the angle opposite, dividing the triangle into two right-angled triangles. Find the difference of the segments of the base by Theorem III.; half this difference added to half the base gives the greater segment, and subtracted from half the base gives the less. We will then have two sides and the right angle of two right-angled triangles, from which we can find the acute angles by Theorem I.

EXAMPLES.

1. In a triangle ABC, given AB = 60, AC = 50, and BC = 40, to find the angles.

Solution.-Let ABC represent the triangle; then AB = 60, AC = 50, BC = 40; then, by Th. III.,

$$AB: AC + BC: AC - BC: AD - BD,$$
 or, 60: 90 :: 10 : $AD + BD$.

hence,
$$AD - BD = 90 \times 10 \div 60 = 15$$
;

then,
$$AD = \frac{1}{2}(60 + 15) = 37.5$$

and $BD = \frac{1}{2}(60 - 15) = 22.5$

Then, in the triangle ACD, to find the angle ACD,

a. c.
$$AC$$
 (50) 8.301030
: AD (37.5) 1.574031
:: $\sin D$ (90°) 10.000000
: $\sin ACD$ 48° 35′ 25″ 9.875061

PLANE TRIGONOMETRY.

29

Then, in the triangle BCD, to find the angle BCD,

a. c.	BC	(40)	8.397940
	: <i>BD</i>	(22.5)	1.352183
100	$: \sin D$	(90°)	10.000000
1 1	JINC	PIVI	

: sin BCD 34° 13′ 44″ 9.750123

Hence, $A = 90^{\circ} - 48^{\circ} 35' 25'' = 41^{\circ} 24' 35''$, and $B = 90^{\circ} - 34^{\circ} 13' 44'' = 55^{\circ} 46' 16''$,

and $C = 48^{\circ} 35' 25'' + 34^{\circ} 13' 44'' = 82^{\circ} 49' 09''.$

2. In a plane triangle the sides are 1005, 1210, and 1368; required the angles.

Ans. 45° 22' 35"; 58° 58' 18"; 75° 39' 7".

SOLUTION OF RIGHT-ANGLED TRIANGLES.

- 44. In the solution of right-angled triangles we have the four following cases:
- 1. When the hypothenuse and an acute angle are given.
- 2. When the hypothenuse and a side are given.
- 3. When one side and the angles are given.
- 4. When the two sides about the right angle are given.

Метнор.—The first three cases are readily solved by Theorem

- ..; remembering that the sine of 90° is radius, the log. sin. being
- 10. The fourth case may be solved by Theorem V.; or we may find the hypothenuse by B. III. Th. VI., and then find the angles by Theorem I.

These four cases may also be solved by Theorems IV. and V.; but the method suggested above is preferred, since it is simpler and more easily remembered.

EXAMPLES.

1. In a right-angled triangle, given the hypothenuse 475 and the angle at the base 36° 34′; find the other parts.

Solution.—Let CAB represent the triangle, BC being equal to 475 and the angle $C = 36^{\circ}34'$; then, to find

AB, we hav	e,				
sin A	90°	a. c.	0.000000		
: sin C	36° 34′		9.775070	/x	
;: CB	475		2.676694	Ó	A
: AB	282.985		2.451764		

The angle $B = 90^{\circ} - (36^{\circ} 34') = 53^{\circ} 26$; then, by a similar proportion, we can find the side CA = 381.503.

- 2. Given the hypothenuse 45.36 and the angle at the base 45° 36'; required the other parts.

 Ans.
- 3. Given the hypothenuse 396 and the base 218, to find the other parts.

 Ans. 330.59; 33° 24′ 05″; 56° 35′ 55″.
- 4. Given the two sides 58.75 and 74.58, to find the remaining parts,

 Ans. 94.94; 38° 13′ 45″; 51° 46′ 15″.

PRACTICAL APPLICATIONS.

HEIGHTS AND DISTANCES.

- 45. A HORIZONTAL PLANE is one which is parallel to the plane of the horizon.
- 46. A VERTICAL PLANE is one which is perpendicular to a horizontal plane.
- 47. A HORIZONTAL LINE is any line in a horizontal plane. A vertical line is a line perpendicular to a horizontal plane.
- 48. A HORIZONTAL ANGLE is an angle in a horizontal plane.
- 49. A VERTICAL ANGLE is an angle in a vertical plane.
- 50. An Angle of Elevation is a vertical angle having one

side horizontal, and the inclined side above \underline{c} the horizontal side; as BAD.

- 51. An Angle of Depression is a vertical angle having one side horizontal, and the inclined side under the horizontal side; as CDA.
- 52. Distances upon the ground are usually measured by a chain, called Gunter's Chain. This chain is 4 rods or 66 feet long, and consists of 100 links. Sometimes a half chain is used, consisting of 50 links.
- 53. Angles are measured by various instruments. Horizontal angles are measured by an instrument called *The Compass*. Horizontal and vertical angles are both measured by the *Theodolite*, or, what is still better for general use, a *Transit-Theodolite*.

CASE I.

54. To determine the height of a vertical object standing upon a horizontal plane.

Mernon.—Measure from the foot of the object any convenient horizontal distance AB; at the point A take the angle of elevation BAC; then, in the triangle ABC we have a side and an acute angle; hence, we can readily find the altitude.

Ans. 136.113 feet.

CASE II.

55. To find the distance of a vertical object whose height is known.

METHOD.—Measure the angle of elevation to the top of the object, as before; we will then have a right-angled triangle in

1. I took the angle of elevation to the top of a flag-staff whose height I knew to be 160 feet, and found it to be 20°; how far was I from the staff?

Ans. 439.60 feet.

CASE III.

56. To find the distance of an inaccessible object.

METHOD.—Measure a horizontal base-line AB, and then take

the angles formed by this line and lines from the object to the extremities of this base-line, as CAB and ABC; the distance AC or BC can then be readily found.

1. I am on one side of a river, and wish to know the distance to a tree on the other side. I measure 300 yards by the side of the river, and find that the two

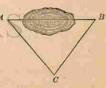

Ans. 243.362 yards; 325.15 yards.

57. To find the distance between two objects separated by an impassable barrier.

Метнор.—Select any convenient station, as C, and measure the distance from it to each of the objects A and B, and the angle C included between these lines. We can then readily find the distance AB.

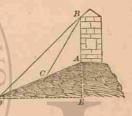

32

which each of the trees can be seen, and find the distances from it to the trees to be 300 and 250 yards, and the included angle 43° 16'; required the distance between the trees.

Ans. 208.02 yards.

58. To find the height of a vertical object standing upon an inclined plane.

METHOD. - Measure any convenient distance AD on a line from the foot of the object, and at the point D measure the angles of elevation, EDA and EDB, to foot and top of the tower. By means of the two triangles DEA and DEB, we can find the height of AB.

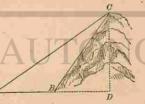

1. Wishing to determine the height of a tower situated upon a hill, I measured a distance down the slope of the hill 400 feet, and found the angles of elevation to the foot of the tower 42° 28', and to the top of the tower 68° 42'; required the height of the Ans. 486,747. tower.

CASE VI.

59. To find the height of an inaccessible object above a horizontal plane.

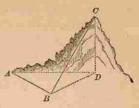

FIRST METHOD. - Measure any convenient horizontal line AB directly toward the object, and take the angles of elevation at A and B; we will then have conditions sufficient to find DC.

1. Wishing to find the altitude of a hill, I measured the angle of elevation at the bottom 60° 37', and 460 feet from the foot in a right line of the top of the hill and the point at the foot, and in the same horizontal plane as the foot, I measured the angle of elevation 36° 52'; required the height of the hill.

Second Method.—If it is not convenient to measure a horizontal base-

tine towards the object, we measure any line AB, and also measure the horizontal angles BAD, ABD, and the angle of elevation DBC. Then, by means of the two triangles ABD and CBD, the height CD can be found.

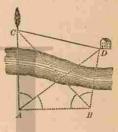

CASE VII.

60. To find the distance between two inaccessible objects when points can be found at which both objects can be seen.

Метнор.—The method of measurement is indicated in the following problem. The method of solution we prefer leaving to the ingenuity of the pupil, that he may learn to think for himself.

1. Wishing to know the horizontal distance between a tree and house on the opposite side of a river, I took the following measurements:

$$AB = 400$$
; $CAD = 56^{\circ}$ 30',
 $BAD = 42^{\circ}$ 24'; $ABC = 44^{\circ}$ 36',
and $DBC = 68^{\circ}$ 50'.

Required the distance CD.

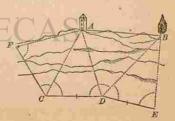

Ans. 747.913.

CASE VIII.

61. To find the distance between two inaccessible objects when no points can be found from which both objects can be seen.

Метнор.—The method is indicated in the following problem and figure. This and the following case may be omitted with young pupils.

1. Wishing to know the horizontal distance between two in-

accessible objects when no point can be found from which both objects can be seen, two objects C and D are taken, 600 feet apart, from the former of which A can be seen, from the latter B. From C we measure the distance CF, not in the direction DC, equal to 600 feet, and from D a distance DE equal to 600 feet. We then measure the following angles:

CFA = 80° 16′, BED = 86° 25′, ACF = 52° 24′, BDE = 60° 24′, ACD = 56° 36′, BDC = 150° 30′.

Required the distance AB.

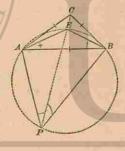

Ans. 1117.44 feet.

CASE IX.

62. To find the distances from a given point to three objects whose distances from each other are known.

Метнор.—The method is indicated in the problem and figure.

1. I wish to locate three buoys, A, B, and C, in a harbor, so that the distance between A and B is 800 yards, between A and C 600 yards, between B and C 400 yards, and from a fixed point on shore, the angle APC shall equal 33° 45′, and BPC 22° 30′; required the distances PA, PC, and PB.

Ans. PA = 710.193; PC = 1042.522; PB = 934.291.

DIRECCIÓN GENERAL

Nore.—This last problem is given by quite a number of authors, and seems to be general property.

ANALYTICAL TRIGONOMETRY.

- 63. ANALYTICAL TRIGONOMETRY is that branch of Mathematics which treats of the properties and relations of trigonometrical functions.
- 64. Trigonometry, in its origin, was confined to triangles, the method of reasoning being geometrical. After the invention of analysis, mathematicians began to apply it to trigonometry, and, in course of time, developed the general properties of trigonometrical functions. This has enlarged the science and greatly increased its power as an instrument of investigation and discovery.

DEFINITIONS.

- 63. A circumference consists of four quadrants. AB is the first quadrant; BC is the second quadrant, etc.
- 66. The *origin* of arcs is at A, all arcs being generally supposed to begin at A.
- 67. The extremity of an arc is where it ends. An arc is said to be in that quadrant where its extremity is situated.

68. The sine, cosine, tangent, cotangent, etc. of an arc have already been defined,

and need not be repeated here. The versed sine of an arc is the distance from the foot of the sine to the origin of the arc. The coversed sine is the versed sine of the complement.

The sines, cosines, etc. are called the circular functions of the arcs.

- 69. Fundamental formulas expressing the relation between the circular functions of any arc.
- 1. Let a represent the measuring arc of any angle. Draw the lines represented in the figure. Then, from the definitions,

accessible objects when no point can be found from which both objects can be seen, two objects C and D are taken, 600 feet apart, from the former of which A can be seen, from the latter B. From C we measure the distance CF, not in the direction DC, equal to 600 feet, and from D a distance DE equal to 600 feet. We then measure the following angles:

CFA = 80° 16′, BED = 86° 25′, ACF = 52° 24′, BDE = 60° 24′, ACD = 56° 36′, BDC = 150° 30′.

Required the distance AB.

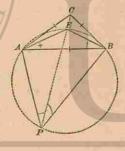

Ans. 1117.44 feet.

CASE IX.

62. To find the distances from a given point to three objects whose distances from each other are known.

Метнор.—The method is indicated in the problem and figure.

1. I wish to locate three buoys, A, B, and C, in a harbor, so that the distance between A and B is 800 yards, between A and C 600 yards, between B and C 400 yards, and from a fixed point on shore, the angle APC shall equal 33° 45′, and BPC 22° 30′; required the distances PA, PC, and PB.

Ans. PA = 710.193; PC = 1042.522; PB = 934.291.

DIRECCIÓN GENERAL

Nore.—This last problem is given by quite a number of authors, and seems to be general property.

ANALYTICAL TRIGONOMETRY.

- 63. ANALYTICAL TRIGONOMETRY is that branch of Mathematics which treats of the properties and relations of trigonometrical functions.
- 64. Trigonometry, in its origin, was confined to triangles, the method of reasoning being geometrical. After the invention of analysis, mathematicians began to apply it to trigonometry, and, in course of time, developed the general properties of trigonometrical functions. This has enlarged the science and greatly increased its power as an instrument of investigation and discovery.

DEFINITIONS.

- 63. A circumference consists of four quadrants. AB is the first quadrant; BC is the second quadrant, etc.
- 66. The *origin* of arcs is at A, all arcs being generally supposed to begin at A.
- 67. The extremity of an arc is where it ends. An arc is said to be in that quadrant where its extremity is situated.

68. The sine, cosine, tangent, cotangent, etc. of an arc have already been defined,

and need not be repeated here. The versed sine of an arc is the distance from the foot of the sine to the origin of the arc. The coversed sine is the versed sine of the complement.

The sines, cosines, etc. are called the circular functions of the arcs.

- 69. Fundamental formulas expressing the relation between the circular functions of any arc.
- 1. Let a represent the measuring arc of any angle. Draw the lines represented in the figure. Then, from the definitions,

AB = 1, $BE = \tan \alpha$,

 $CD = \sin a$, $AE = \sec a$,

 $AD = \cos a$, $DB = \operatorname{ver} \sin a$.

In the right-angled triangle ADC, we have, $\overline{CD^2} + \overline{AD^2} = AC^2$, or, by substitution,

 $\sin^2 a + \cos^2 a = 1.$ (1) Hence, $\sin^2 a = 1 - \cos^2 a$; (2) $\cos^2 a = 1 - \sin^2 a$. (3)

2. From the figure, we also have,

DB = AB - AD; that is, ver $\sin a = 1 - \cos a$. (4)

Since this is true for any value of a, it is true for $90^{\circ} - a$;

hence, $\text{ver sin } (90^{\circ} - a) = 1 - \cos (90^{\circ} - a),$

 $co-ver \sin a = 1 - \sin a. \tag{5}$

3. Again, the triangles ADC and ABE being similar,

EB:AB::CD:AD,

or, $\tan a:1::\sin a:\cos a;$

hence, $\tan \alpha = \frac{\sin \alpha}{\cos \alpha}$ (6)

Substituting $90^{\circ} - a$ for a, we have,

$$\tan (90^{\circ} - a) = \frac{\sin (90^{\circ} - a)}{\cos (90^{\circ} - a)},$$

or, $\cot a = \frac{\cos a}{\sin a}$.

4. Again, multiplying equations (6) and (7), we have,

 $\tan a \cot a = 1; \tag{8}$

tan $a = \frac{1}{\cot a}$ (9), and $\cot a = \frac{1}{\tan a}$ (10)

5. Again, from the same triangles, we have,

AE:AB::AC:AD,

or, sec a: 1::1: cos a;

nence, $\sec a = \frac{1}{\cos a}$ (1

Substituting 90° — a for a,

$$\sec{(90^{\circ}-a)} = \frac{1}{\cos{(90^{\circ}-a)}}$$

or, $\csc a = \frac{1}{\sin a}$ (12)

6. Again, from the triangle ABE, we have,

 $\sec^2 a = 1 + \tan^2 a; \tag{13}$

hence, $\csc^2 a = 1 + \cot^2 a$. (14)

70. These are the fundamental formulas of trigonometry, and should be committed to memory. We will collect them, forming the following table:

TABLE I. .

 Sin²a Sin²a 	$+\cos^2 a = 1$	1 — cos² a	9. Tan a	=	$\frac{1}{\cot a}$
3. Cos² a		$-\sin^2 a$	10. Cot a	=	$\frac{1}{\tan a}$
4. Ver sin 5. Co-ver		$-\cos a$ $-\sin a$	11. Sec a	=	$\frac{1}{\cos a}$
6. Tan a		$\frac{\sin a}{\cos a}$	12. Co-sec a		$\frac{1}{\sin a}$
7. Cot a	=	$\frac{\cos a}{\sin a}$	13. See ² a		$1 + \tan^2 a$
8. Tan a	cot a =	1	14. Co-sec ² a	=	$1 + \cot^2 a$

ALGEBRAIC SIGNS OF THE CIRCULAR FUNCTIONS.

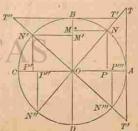

71. In analytical trigonometry, we regard the algebraic signs of the functions as well as their numerical value. The sign of a function is determined by the following principles.

All lines estimated upward from the horizontal diameter are POSITIVE;
 all lines estimated downward from it are NEGATIVE.

2. All lines estimated from the vertical diameter towards the right are POSITIVE; all lines estimated toward the left are NEGATIVE.

Thus, the sines NP and N'P' are positive, while N''P'' and N'''P''' are negative; so also the cosines OP and OP''' are positive, while OP' and OP'' are negative.

72. The simplest way to determine the algebraic signs of the different functions is to derive those of the sine and cosine from the figure, and the others from the formulas.

1. The Sine is positive in the first and second quadrants, being measured above, and negative in the third and fourth quadrants.

2. The Cosine is positive in the first and fourth quadrants, and negative in the second and third quadrants.

3. The TANGENT is positive in the first and third quadrants, and negative in the second and fourth.

For, from formula (6),

VERITATIS
$$\tan a = \frac{\sin a}{\cos a}$$

and this is positive when sine and cosine have like signs, and negative when they have unlike signs. In the first quadrant, both sine and cosine are plus, in the third both are minus, in the second and fourth one is plus and the other minus; hence, the tangent is positive in the first and third quadrants and negative in the second and fourth.

4. The Cotangent is positive in the first and third quadrants, and negative in the second and fourth; as is readily shown from the formula.

$$\cot a = \frac{\cos a}{\sin a}.$$

5. The SECANT is positive in the first and fourth quadrants, and negative in the second and third. For, from formula (11),

$$\sec a = \frac{1}{\cos a}$$

hence, the secant has the same sign as the cosine.

6. The Co-secant is positive in the first and second quadrants and negative in the third and fourth, as may be shown from For. (12).

Note.—Some of these may also be readily shown from the figure. In the secont, when the distance is estimated toward the extremity of the arc, it is plus; when from the extremity, minus.

LIMITING VALUES OF THE CIRCULAR FUNCTIONS.

73. The limiting values of the circular functions are their values at the beginning and end of the different quadrants.

These values are determined by the principle that the value of a variable quantity up to the limit is its value at the limit.

Beginning at the origin, we see that the value of $\sin 0$ is 0, and the $\cos 0$ is the radius, or 1. As the arc increases, the sine increases and the cosine decreases, until at 90° the sine is 1 and the cosine 0. As the arc increases from 90° to 180°, the sine decreases and cosine increases numerically (diminishes algebraically), until at 180° the sine is +0 and $\cos -1$. In the same way we see that $\sin 270^{\circ} = -1$, and $\cos 270^{\circ} = -0$; also, $\sin 360^{\circ} = -0$, and $\cos 360^{\circ} = 1$.

Now, since, by formula (6),

$$\tan a = \frac{\sin a}{\cos a},$$
substituting 0 for a,
$$\tan 0 = \frac{\sin 0}{\cos 0} = \frac{0}{1} = 0;$$
and, also,
$$\cot 0 = \frac{\cos 0}{\sin 0} - \frac{1}{0} = \infty.$$

74. By a similar examination of the limiting values of all the functions, we have the following table:

TABLE II.

Arc = 0	Arc	90° Are	= 180°	Arc = 270°	Arc = 360°
sin = cos = v-sin = tan = cot = sec = cosec =	0 sin = 1 cos = 0 v-sin = 1 co-v-sin = 0 tan = 0 cot = 1 sec = 0 cosec = 0	0 cos 1 v-sin 0 co-v-sii o tan 0 cot o sec	$ \begin{array}{rcl} $	os = - -sin = o-v-sin = on = ot = ec = - o	$ \begin{array}{cccccccccccccccccccccccccccccccccccc$

FUNCTIONS OF THE SUM OR DIFFERENCE OF AN ARC AND ANY NUMBER OF QUADRANTS.

75. The trigonometrical function of any are formed by adding an arc to or subtracting it from any number of quadrants, may be expressed in functions of the arc which is added to or subtracted from.

1. Let a represent any arc less than 90°; then, from the definitions, we have,

 $\sin^{2}(90^{\circ} - a) = \cos a, \qquad \cot^{2}(90^{\circ} - a) = \tan a,$ $\cos(90^{\circ} - a) = \sin a, \qquad \sec^{2}(90^{\circ} - a) = \csc a,$ $\tan(90^{\circ} - a) = \cot a, \qquad \csc(90^{\circ} - a) = \sec a.$

2. Now, let a represent the arc BN', then will $ABN' = 90^{\circ} + a$. From the figure, Art. 71, we see that

$$N'M' = \sin a,$$
 $M'O = \cos a,$ $P'O = \cos (90^{\circ} + a),$ $N'P' = \sin (90^{\circ} + a).$

Hence, remembering that ABN', being in the second quadrant, its cosine is negative, we have,

$$\sin (90^{\circ} + a) = \cos a$$
, and $\cos (90^{\circ} + a) = -\sin a$.

Substituting these values in the formulas for tan, cot, etc. found in Table I., we have,

$$\tan (90^{\circ} + a) = -\cot a$$
, $\sec (90^{\circ} + a) = -\csc a$, $\cot (90^{\circ} + a) = -\tan a$, $\csc (90^{\circ} + a) = -\sec a$.

3. Again, let a represent the arc CN, then will ABN=180-a. From the figure, we have,

$$N'P' = \sin a,$$
 $P'O = \cos a,$ $N'P' = \sin (180 - a),$ $P'O = \cos (180 - a).$

Hence, remembering that the cosine of ABN' ending in the second quadrant is negative, we have,

$$\sin(180^{\circ} - a) = \sin a$$
, and $\cos(180^{\circ} - a) = -\cos a$.

Substituting these values in the formulas for tan, cot, etc. in Table I., we have,

$$\tan (180^{\circ} - a) = -\tan a$$
, sec $(180^{\circ} - a) = -\sec a$, $\cot (180^{\circ} - a) = -\cot a$, $\csc (180^{\circ} - a) = -\csc a$.

From the above, we see that the sine of an arc equals the sine of its supplement, and the cosine of an arc equals minus the cosine of its supplement, etc.

76. In a similar manner, by deriving the values of the sines and cosines from the figure and making the substitutions in the proper formulas, we may obtain the functions of $180^{\circ} + a$, $270^{\circ} - a$, $270^{\circ} + a$, and $360^{\circ} - a$. All of these, with the above, are exhibited in the following table:

TABLE III.

Arc = 270° - a. $Arc = 90^{\circ} + a$ $\sin = \cos a$, $\cot = -\tan a$, $\sin = -\cos a$, $\cot = \tan a$, $\cos = -\sin a$, $\sec = -\csc a$, $\cos = -\sin a$, $\sec = -\csc a$, tan = cot a, cosec = - sec a. $tan = -\cot a$, $cosec = -\sec a$. Arc = 270° + a. Are = 1800 - a. $\sin = -\cos a$, cot = $-\tan a$, $\sin = \sin a$, $\cot = -\cot a$, cos = sin a, sec = cosec a, $\cos = -\cos a$, $\sec = -\sec a$, tan = -tan a, cosec = cosec a, tan = -cot a, cosec = -sec a. Arc = 360° - a. $Arc = 180^{\circ} + a$. $\sin = -\sin a$, $\cot = \cot a$, $\sin = -\sin a$, $\cot = -\cot a$, $\cos = -\cos a$, $\sec = -\sec a$, $\cos = -\cos a$, $\sec = -\sec a$, $\tan a$, $\csc = -\csc a$. $\tan = -\tan a$, $\csc = -\csc a$.

77. This table can easily be committed to memory, by observing that when the arc is connected with 180° or 360°, the functions in both columns have the same name; but when connected with 90° or 270°, the functions in the two columns have different names.

78. The principles of this table are of great value. By their means the functions of any arc may be expressed in functions of an arc less than 90°. Thus,

$$\sin 120^{\circ} = \sin (90^{\circ} + 30^{\circ}) = \cos 30^{\circ},$$

 $\tan 243^{\circ} = \tan (180^{\circ} + 63^{\circ}) = \tan 63^{\circ},$
 $\cot 304^{\circ} = \cot (270^{\circ} + 34^{\circ}) = -\tan 34^{\circ}.$

79. When the arc is greater than 360°, we may subtract 360° one or more times until we obtain an arc less than 360°; the remainder will have the same origin and extremity: hence, the circular function of the remainder will be the same as of the given arc, and this remainder being less than 360°, its functions can be expressed in functions of an arc less than 90°. Hence, the functions of any arc can be expressed in functions of an arc less than 90°.

CIRCULAR FUNCTIONS OF NEGATIVE ARCS.

80. Suppose AB to be any arc, and AC, estimated from the origin downward, be numerically equal to AB; then, if the arc AB be denoted by a, the arc AC will be denoted by -a: and CD will be the sine, and OD the cosine, of -a.

Now, since BD = CD and OD is the cosine of both a and -a.

$$\sin (-a) = -\sin a$$
, and $\cos (-a) = \cos a$.

Substituting these in the formulas of Table I., we will have,

ver sin
$$(-a) =$$
 ver sin a , cot $(-a) =$ cot a , co-ver sin $(-a) = 1 + \sin a$, sec $(-a) =$ sec a , tan $(-a) =$ -tan a , co-sec $(-a) =$ -co-sec a .

81. From what has now been presented, we see that the circular functions of all arcs, whether positive or negative, may be expressed in functions of arcs less than 90°; hence, in the table of sines, cosines, etc., we have only positive arcs and those less than

RELATION OF THE SIDES AND FUNCTIONS OF RIGHT-ANGLED

82. Let ACB be a right-angled triangle, the right angle being at A. Represent the angles by A, B, C, and their opposite sides by a, b, c. With a radius CE = 1, describe the arc EF, and draw the perpendicular ED; then $ED = \sin C$, and CD = cos C.

Now, from the figure, we readily obtain,

and, also,
$$1: \operatorname{sir} C:: a: c,$$

$$1: \cos C:: a: b;$$
 hence,
$$\sin C = \frac{c}{a} \qquad (1), \cos C = \frac{b}{a} \qquad (2),$$
 or,
$$c = a \sin C \qquad (3), \ b = a \cos C \qquad (4).$$

Dividing (1) by (2) and then (2) by (1), we have,

$$\tan C = \frac{c}{b}$$
 (5), $\cot C = \frac{b}{c}$ (6),

 $c = b \tan C(7)$, and $b = c \cot C(8)$.

83: These the pupil will commit to memory, and also translate into common language. The first, thus translated, is as follows:

1. The sine of either acute angle of a right-angled triangle is equal to the opposite side divided by the hypothenuse.

84. General formulas relating to the sum and difference OF ARCS, DOUBLE ARCS, ETC.

1. Let AB and BC be two arcs having the common radius OA or OC=1; denote AB by b and BC by a. From C draw CD perpendicular to OA, and CN perpendicular to OB; from N draw NE perpendicular to OA, and NM parallel to OA. Then,

$$CD=\sin{(a+b)},\ CN=\sin{a},\ ON=\cos{a}.$$
 Now, $CD=CM+NE.$ In the triangle $OEN,$

$$NE = ON \sin B = \cos a \sin b;$$

since CMN and NOE are similar, and the angle MCN = NOE = b.

$$CM = CN \cos b = \sin a \cos b$$
.

Substituting these values in equation (1), we have,

$$\sin (a+b) = \sin a \cos b + \cos a \sin b$$
. (A)

This formula expresses the value of the sine of the sum of two arcs in terms of the sine and cosine of the single arcs. It is enunciated as follows:

The sine of the sum of two ares or angles is equal to the sine of the first into the cosine of the second, plus the cosine of the first into the sine of the

2. If in formula (A) we substitute - b for b, we have,

$$\sin(a-b) = \sin a \cos(-b) + \cos a \sin(-b);$$

but (Art. 80)
$$\cos(-b) = \cos b$$
, and $\sin(-b) = -\sin b$;
hence, $\sin(a-b) = \sin a \cos b - \cos a \sin b$. (B)

3. If in formula (B) we substitute $90^{\circ} - a$ for a, we have,

$$\sin (90^{\circ} - a - b) = \sin (90^{\circ} - a) \cos b - \cos (90^{\circ} - a) \sin b;$$

but,
$$\sin(90^{\circ} - a - b) = \sin(90^{\circ} - (a + b)) = \cos(a + b)$$
,

and,
$$\sin(90^{\circ} - a) = \cos a$$
, and $\cos(90 - a) = \sin a$;

hence,
$$\cos(a+b) = \cos a \cos b - \sin a \sin b$$
. (C)

4. Substituting -b for b in formula (C), we have,

$$\cos(a-b) = \cos a \cos(-b) - \sin a \sin(-b),$$

or,
$$\cos(a-b) = \cos a \cos b + \sin a \sin b$$
. (D)

5. From Table I., For. (6), and formulas (A) and (C), we have,

$$\tan (a+b) = \frac{\sin (a+b)}{\cos (a+b)} = \frac{\sin a \cos b + \cos a \sin b}{\cos a \cos b - \sin a \sin b}$$

Dividing both terms of the last member by cos a cos b, we have,

$$\tan (a + b) = \frac{\sin a \cos b}{\cos a \cos b} + \frac{\cos a \sin b}{\cos a \cos b}$$

$$1 = \frac{\sin a \sin b}{\cos a \cos b}$$

Cancelling common factors, and reducing, we have,

$$\tan (a+b) = \frac{\tan a + \tan b}{1 - \tan a \tan b}.$$
 (E)

6. Substituting -b for b in formula (E), and reducing, we have,

$$\tan (a-b) = \frac{\tan a - \tan b}{1 + \tan a \tan b}.$$
 (F)

7. Dividing formula (C) by (A), and reducing as in (5), we have,

$$\cot(a+b) = \frac{\cot a \cot b - 1}{\cot b + \cot a}.$$
 (G)

8. Substituting - b for b in formula (G), and reducing, we have

$$\cot(a-b) = \frac{\cot a \cot b + 1}{\cot b - \cot a}.$$
 (H)

S5. FORMULAS FOR DOUBLE AND HALF ARCS.

1. Making a = b in formulas (A), (C), (E), and (G), we have,

$$\sin 2a = 2\sin a \cos a; \tag{A'}$$

$$\cos 2 a = \cos^2 a - \sin^2 a, \qquad (C'$$

$$\tan 2 a = \frac{2 \tan a}{1 - \tan^2 a} \tag{E'}$$

$$\cot 2a = \frac{\cot^2 a - 1}{2 \cot a}. \tag{G'}$$

2. If now in (C') we put $1 - \sin^2 a$ for $\cos^2 a$, and then $1 - \cos^2 a$ for $\sin^2 a$, we have,

$$\cos 2a = 1 - 2\sin^2 a,$$
 (1)

$$\cos 2a = 2\cos^2 a - 1,$$
 (2)

from which we have,

$$\sin a = \sqrt{\frac{1 - \cos 2a}{2}}, \qquad (A^{\prime\prime})$$

$$\cos a = \sqrt{\frac{1 + \cos 2 a}{2}}.\tag{C"}$$

Dividing (A'') by (C'') and then (C'') by (A''), multiplying numerator and denominator by the denominator, and reducing,

$$\tan a = \frac{\sin 2 a}{1 + \cos 2 a'} \tag{E''}$$

$$\cot a = \frac{\sin 2 a}{1 - \cos 2 a}.$$
 (G")

3. Now, substituting \(\frac{1}{2}\) a for a in (A''), (C''), (E''), and (G''),

$$\sin \frac{1}{2} a = \sqrt{\frac{1 - \cos a}{2}}, \qquad (A_1)$$

$$\cos \frac{\pi}{2} a = \sqrt{\frac{1 + \cos a}{2}}, \qquad (C_1)$$

$$\tan \frac{1}{2} a = \frac{\sin a}{1 + \cos a}$$
 (E_i)

$$\cot \frac{1}{2} a = \frac{\sin a}{1 - \cos a}.$$
 (G₁)

Taking the reciprocals of (Ei) and (Gi), we have,

$$\cot \frac{1}{2}a = \frac{1 + \cos a}{\sin a}, \quad (E_n)$$

$$\tan \frac{1}{4} a = \frac{1 - \cos a}{\sin a}.$$
 (G_n)

86. Additional formulas.

1. Adding and subtracting formulas (A) and (B), and doing the same with (C) and (D), we have,

$$\sin(a+b) + \sin(a-b) = 2\sin a \cos b, \tag{1}$$

$$\sin(a+b) = \sin(a-b) = 2\cos a \sin b, \tag{2}$$

$$\cos(a+b) + \cos(a-b) = 2\cos a \cos b, \qquad (3)$$

$$\cos(a-b) - \cos(a+b) = 2\sin a \sin b. \tag{4}$$

2. Now, making

$$a+b=p$$
 and $a-b=q$.

whence,

$$a = \frac{1}{2}(p+q) \text{ and } b = \frac{1}{2}(p-q);$$

and substituting these in the above, and we have,

$$\sin p + \sin q = 2 \sin \frac{1}{2} (p+q) \cos \frac{1}{2} (p-q),$$
 (K)

$$\sin p - \sin q = 2\cos \frac{1}{2}(p+q)\sin \frac{1}{2}(p-q),$$
 (L)

$$\cos p + \cos q = 2\cos \frac{1}{2}(p+q)\cos \frac{1}{2}(p-q),$$
 (M)

$$\cos q - \cos p = 2\sin \frac{1}{2}(p+q)\sin \frac{1}{2}(p-q).$$
 (N)

3. Now, dividing (K) by (L),

$$\frac{\sin p + \sin q}{\sin p - \sin q} = \frac{\sin \frac{1}{2} (p+q) \cos \frac{1}{2} (p-q)}{\cos \frac{1}{2} (p+q) \sin \frac{1}{2} (p-q)} = \frac{\tan \frac{1}{2} (p+q)}{\tan \frac{1}{2} (p-q)}.$$
 (P

In a similar manner, we obtain

$$\frac{\sin p + \sin q}{\cos p + \cos q} = \frac{2\sin \frac{1}{2}(p+q)\cos \frac{1}{2}(p-q)}{2\cos \frac{1}{2}(p+q)\cos \frac{1}{2}(p-q)} = \tan \frac{1}{2}(p+q), \quad (Q)$$

$$\frac{\sin p - \sin q}{\cos p + \cos q} = \frac{2 \sin \frac{1}{2} (p - q) \cos \frac{1}{2} (p + q)}{2 \cos \frac{1}{2} (p + q) \cos \frac{1}{2} (p - q)} = \tan \frac{1}{2} (p - q), \text{ (R)}$$

$$\frac{\sin p + \sin q}{\sin (p+q)} = \frac{2\sin \frac{1}{2}(p+q)\cos \frac{1}{2}(p-q)}{2\sin \frac{1}{2}(p+q)\cos \frac{1}{2}(p+q)} = \frac{\cos \frac{1}{2}(p-q)}{\cos \frac{1}{2}(p+q)}, \quad (S.1)$$

$$\frac{\sin p - \sin q}{\sin (p+q)} = \frac{2 \sin \frac{1}{2} (p-q) \cos \frac{1}{2} (p+q)}{2 \sin \frac{1}{2} (p+q) \cos \frac{1}{2} (p+q)} = \frac{\sin \frac{1}{2} (p-q)}{\sin \frac{1}{2} (p+q)}, \quad (T)$$

$$\frac{\sin{(p-q)}}{\sin{p} - \sin{q}} = \frac{2\sin{\frac{1}{2}(p-q)}\cos{\frac{1}{2}(p-q)}}{2\sin{\frac{1}{2}(p-q)}\cos{\frac{1}{2}(p+q)}} = \frac{\cos{\frac{1}{2}(p-q)}}{\cos{\frac{1}{2}(p+q)}} = \frac{\cos{\frac{1}{2}(p-q)}}{\cos{\frac{1}{2}(p+q)}}.$$
 (U)

These formulas may be enunciated in propositions; thus formula (P) gives,

The sum of the sines of two arcs is to the difference of their sines as the tangent of one-half of the sum of the arcs is to the tangent of one-half of their difference.

Comparing (S) and (U), we have,

$$\frac{\sin(p-q)}{\sin p - \sin q} = \frac{\sin p + \sin q}{\sin(p+q)}.$$

Hence, the sine of the difference of two arcs is to the difference of their sines as the sum of the sines is to the sine of the sum.

INTRODUCTION OF THE RADIUS.

87. In the preceding formulas, the radius, being unity, does not appear in any of the terms. When the radius is other than a unit, it should appear in these formulas, and we will now show how it may be introduced.

Let a be an arc whose radius is 1, and a' be an arc whose radius is R; then, by similar triangles,

$$\sin a : \sin a' :: 1 : R;$$
hence, $\sin a' = R \times \sin a$; $\sin a = \frac{\sin a'}{R}$;

and the same may be shown for the other circular functions.

Therefore, any circular function whose radius is R is equal to the circular function whose radius is 1, multiplied by R.

Also, any circular function whose radius is 1 is equal to the circular function whose radius is R, divided by R.

Now, if we substitute these in any of the formulas, we will find that R will be introduced in such a manner as to make the formulas homogeneous. Thus, For. 6, Tab. I., gives,

$$\frac{\tan a'}{R} = \frac{\frac{\sin a'}{R}}{\frac{\cos a'}{R}}; \text{ or, } \tan a' = \frac{R \sin a'}{\cos a'}.$$

Here, $\tan \alpha'$ is a line, and $R \sin \alpha' + \cos \alpha'$ is a surface divided by a line, which is also a line; hence, the formula is homogeneous. And since the same is generally true, therefore, we can introduce the radius in any formula by multiplying or dividing by R, so as to make the formula homogeneous.

CALCULATION OF A TABLE OF NATURAL SINES.

88. The circumference of a circle whose diameter is 1 is 3.14159 , hence, when the radius is 1, the semi-circumference is 3.14159 ; and if we divide this by 10800, the number of minutes in 180°, the quotient, .000290888 , will be the length of an arc of one minute. Now, this are is so small that it does not differ materially from its sine; hence, we may assume .000290888 as the sine of one minute.

We then find the cosine of 1' by For. 3, Table I. Thus,

$$\cos 1' = \sqrt{1 - \sin^2 1'} = .999999957 \dots$$
 (1)

To find the sine of other arcs, we take the formula under Art. 86, putting it in the form,

$$\sin(a+b) = 2\sin a \cos b - \sin(a-b).$$

Now, make b=1', and then in succession, a equal to 1', 2', 3', etc., and we have,

$$\sin 2' = 2 \sin 1' \cos 1' - \sin 0 = .0005817764 \dots$$

 $\sin 3' = 2 \sin 2' \cos 1' - \sin 1' = .0008726646 \dots$

$$\sin 4' = \text{etc.}$$

We may thus obtain the sines of any number of degrees and minutes up to 45°, the corresponding cosines being obtained from equation (1).

Then, since the sine of an arc equals the cosine of its complement, etc., the sines and cosines of arcs between 45° and 90° are immediately derived from those between 0° and 45°.

The tangents are found by dividing the sines by the cosines; the cotangents are found by dividing the cosines by the sines, or by dividing 1 by the tangents.

CALCULATION OF A TABLE OF LOGARITHMIC SINES.

89. A table of logarithmic sines is computed from a table of natural sines. The process is as follows:

For the logarithmic sine, take the logarithm of the natural sine, and add 10.

For, let $\sin a$ represent the natural sine, and let $\sin a$ represent the sine to a radius of 10,000,000,000; then, Art. 87,

Sin
$$a = \sin a \times R$$
;

taking logarithms, we have,

 $\log \sin a = \log \sin a + \log R$.

But $\log R = \log 10,000,000,000 = 10$.

Hence, $\log \sin a = \log \sin a + 10$.

In the same manner, we find the log cosine; and in a similar manner, from the formulas of Table I., we can find all the other logarithmic circular functions.

THEOREMS AND PROBLEMS.

We now present a few exercises for original thought. The first and third are derived from a diagram; the 5th by For. 2. Art. 84; several which follow, by substituting values from Table I., obtaining an equation involving but one unknown quantity, which can then readily be found; the others, by judicious substitutions and reductions.

- 1. Prove that $\sin 60^{\circ} = \frac{1}{2} \sqrt{3}$, and $\cos 60^{\circ} = \frac{1}{3}$.
- 2. Prove that $\sin 30^{\circ} = \frac{1}{2}$, and $\cos 30^{\circ} = \frac{1}{4} \sqrt{3}$.
- 3. Prove that sin and cos of 45° equal 1 1/2.
- 4. Prove that $\tan 45^{\circ} = 1$, and $\sec 45^{\circ} = \sqrt{2}$.
- 5. Prove $\sin 15^{\circ}$, or $\sin (60^{\circ} 45^{\circ}) = \frac{\sqrt{3} 1}{2\sqrt{2}}$, and $\cos 15^{\circ} = \frac{\sqrt{3} + 1}{2\sqrt{2}}$.
- 6. Prove $\tan 15^{\circ} = 2 \sqrt{3}$, and $\cot 15^{\circ} = 2 + \sqrt{3}$.
- 7. If $\sin a \cos a = \frac{1}{4} \sqrt{3}$ find $\sin a$ and $\cos a$.

Ans.
$$\sin a = \frac{1}{2} \sqrt{3}$$
; $\cos a = \frac{1}{2}$.

Ans. $\tan a = 1$.

- 8. If $3 \sin a + 5 \sqrt{3} \times \cos a = 9$, find $\sin a$. Ans. $\sin a = \frac{1}{2}$ or $\frac{1}{2}$.
- 9. If $\sin a (\sin a \cos a) = \frac{4}{25}$, find $\sin a$.
- 10. If $\tan a = \frac{4}{3}$, find $\sin a$ and $\cos a$. Ans. $\sin a = \frac{4}{3}$; $\cos a = \frac{3}{5}$.
- 11. If $\tan a + \cot a = 2$, find $\tan a$.
- 12. Prove that $\tan^2 a = \sin^2 a = \tan^2 a \sin^2 a$.
- 13. Prove that $\sec^2 a \csc^2 a = \sec^2 a + \csc^2 a$.
- 14. Prove that $\sin (30^{\circ} + a) + \sin (30^{\circ} a) = \cos a$. 15. Prove that $\cos (60^{\circ} + a) + \cos (60^{\circ} - a) = \cos a$.
- 16. If $a + b + c = 180^\circ$, prove that

$$\tan a + \tan b + \tan c = \tan a \tan b \tan c$$

17. If $a+b+c=90^{\circ}$, prove that

$$\cot a + \cot b + \cot c = \cot a \cot b \cot c$$
.

Suggestion.—In 16th, $\tan (a + b) = \tan (180^{\circ} - c)$, develop and simplify; and similarly in 17th.

A TABLE

OF

LOGARITHMIC

SINES AND TANGENTS

FOR EVERY

DEGREE AND MINUTE

OF THE QUADRANT.

Remark. The minutes in the left-hand column of each page, increasing downwards, belong to the degrees at the top; and those increasing upwards, in the right-hand column, belong to the degrees below.

THE

NORMAL EDUCATIONAL SERIES

OF

SCHOOL AND COLLEGE TEXT-BOOKS.

"Every child that comes into the world has a right to an education."
"The dearest interest of a nation is the education of its children."

The art of Teaching, as well as all other arts, is making very rapid progress in this very progressive age. The remarkable growth of Normal Schools, organized to instruct in the best methods of teaching, and employing as professors the most able and advanced educators in the country, has given an immense impetus to the advancement of this most honorable and useful of professions, and almost revolutionized the whole art of teaching. These great changes create a necessity for text-books adapted to them, and the publishers of the above series have taken great pains to meet this necessity. By the aid of their improved text-books, the work of the school-room, instead of being a drudgery, becomes pleasant to teachers and pupils, and they as well as parents are delighted with the rapid progress made with them.

Raub's Normal Primary Speller. Raub's Normal Speller.

Admirably arranged and classified. Simple and easy, yet logical and comprehensive.

Welsh's Practical Grammar.

BY JUDSON PERRY WELSH, A.M.,

PROF. OF ENG. LANGUAGE AND LITERATURE, STATE NORMAL SCHOOL, WEST CHESTER, PA.

Teachers who prefer the use of diagrams will find this an admirable work, in which this popular method of analysis is made clear and simple as possible. It treats of the English Language as it is spoken and written to-day, while tracing its history from older periods. Lessons on Composition and Letter-writing are also given.

Fewsmith's Elementary Grammar. Fewsmith's Grammar of Eng. Language. BY WM. FEWSMITH, A.M., AND EDGAR A. SINGER.

Based on the well-known Murray's System. Easy to understand, the lessons before dreaded become a delight to teacher and pupils. Care has been taken in grading every lesson, modeling tules and definitions, and making every sentence an example of grammatical accuracy.

Publications of CHRISTOPHER SOWER COMPANY, Philadelphia.

Westlake's How to Write Letters.*

This remarkable work of Professor Westlake is a scholarly manual of correspondence, exhibiting the whole subject in a practical form for the school room or private use, and showing the correct Structure, Composition, Punctuation, Formalities and Uses of the various kinds of Letters, Notes and Cards. The articles on Notes and Cards, Titles and Forms of Address and Salutation, are invaluable to every lady and gentleman.

Westlake's Common School Literature.

A scholarly epitome of English and American Literature, containing a vast fund of information. More culture can be derived from it than from many much larger works.

Lloyd's Literature for Little Folks.

The gems of child-literature, arranged to furnish easy lossons in Words, Sentences, Language,
Literature and Composition, united with Object-Lessons. For children in Second Reader.
Handsomely illustrated. The book is the delight of all children.

Pelton's Outline Maps*. Large Size.

These are about 6 by 7 ft. and mounted on ordinary rollers. Price per set of six Maps, \$25.

Pelton's Outline Maps*. Reduced Size.

These are about 416 feet square. Price, on ordinary rollers, Ste per set of six Maps. On spring rollers with handsome campry case, \$13 per set.

- 1. Physical and Political Map of the Western Hemisphere.
- 2. Physical and Political Map of the Eastern Hemisphere.
- Map of the United States, British Provinces, Mexico, Central America and the West India Islands.
- 4, Map of Europe.
- 5. Map of Asia.
- 6. Map of South America and Africa.
- Pelton's Key to full series of Outline Maps.

This beautiful series of Maps is the only set on a large scale exhibiting the main features of Physical in connection with those of Political and Local Geography. Notwithstanding the many outline maps published since Pelion's series originated this method of teaching Geography, the popularity of these elegant maps is undiminished.
