

also be employed. I make use of the following procedure: a pellet of charpie dipped in hydrochloric acid is rubbed upon the affected surface until it causes a superficial wound, and immediately afterwards cauterization is performed with another pellet dipped in a solution of nitrate of silver. The pain produced is not considerable and if the fluid penetrates into healthy tissue, it gives rise to very insignificant injury. The use of caustic pastes is reserved for the deep-spreading or rapidly proliferating forms of cutaneous cancer. Without entering into a comparison of the results following surgical operation and the use of caustic pastes, it may be stated with positiveness that the number of cases which should be treated by the latter means is at least as great as the former. The use of caustic pastes is also indicated strongly in anæmic, cachectic, and old individuals, on account of the trifling loss of blood occasioned thereby.

In neglected cases, which cannot be operated upon, in old individuals, and the like, palliative treatment alone remains. Ulcerations should be kept thoroughly clean and dressed with finely powdered charcoal, chloride of lime, hypermanganate of potash, etc. When a larger blood-vessel is eroded or a considerable parenchymatous hemorrhage takes place, compression may be employed either with dry lint or pieces dipped in chloride of iron. The most important indication for such cases is the relief of pain; this is done by the administration of opium or morphine, either subcutaneously, internally, or applied to the ulceration.
