It is in the direction of abstraction. The ray should close to the hip joint. The hip joint is a ball and socket joint. The acetabulum, the socket, is formed by the hip bone and is deep and strong. It is held in place by the ligaments of the hip joint. The femur, the thigh bone, is connected to the acetabulum by the ligaments of the hip joint. The ligaments of the hip joint are strong and serve to hold the femur in the socket, preventing dislocation. If the dislocation occurs, it is usually a posterior dislocation, where the femur moves backward out of the socket.

In cases of dislocation, the hip joint may need to be reduced surgically. This involves making an incision over the hip and realigning the femur back into the socket. After surgery, the leg may be immobilized in a cast or brace for several weeks to allow healing. Physical therapy is often recommended to help regain strength and range of motion.

If the dislocation is not treated promptly, complications such as avascular necrosis of the femoral head or nerve damage to the sciatic nerve may occur. These complications can lead to long-term pain and disability. Therefore, it is crucial to seek medical attention for dislocated hips as soon as possible. 

In conclusion, dislocated hips require urgent medical attention to prevent serious complications. Early diagnosis and proper treatment are essential to achieving the best outcome.

The primary cause of myalgia, or muscle pain, is often the result of hypoxia, dehydration, malnutrition, and metabolic emergencies. Multifocal involvement of the joint occurs in athletes, being probably a response to a long-continued stress.
